Abstract:

Background: Investigation of the effect of SARS-CoV-2 variants and COVID-19 vaccination on inflammatory and immune response to SARS-CoV-2 infection is limited in South Asia.

Objectives: We aimed to examine the impact of COVID-19 vaccination and waves of COVID-19 on inflammatory and immunological biomarkers among COVID-19 patients in India.

Methods: This cross-sectional analysis used baseline data from a randomized controlled trial of vitamin D and zinc during COVID-19 infection in India (N=181). Blood samples and data regarding vaccination doses were collected. The second (Delta) or third (Omicron) wave was determined by date of enrolment. Mixed effects linear regression with robust standard errors was used to examine associations between COVID-19 vaccination dose or wave at enrolment and C-Reactive Protein (CRP), ferritin, lactate dehydrogenase (LDH), D-dimer, interleukin-6 (IL-6), angiopoietin-2 (Ang-2), soluble triggering receptor expressed on myeloid cells-1 (sTREM-1), immunoglobulin G (IgG) and immunoglobulin M (IgM).

Results: Compared to no vaccination, full vaccination was associated with lower LDH ($P<0.001$), D-dimer ($P=0.521$) and Ang-2 ($P=0.046$), and higher IgG levels ($P<0.001$). Partial vaccination was associated with lower IL-6 ($P=0.040$) and higher IgG ($P<0.001$). Enrolment during the third wave was associated with lower IL-6 ($P<0.001$), CRP ($P=0.056$), IgM ($P=0.013$), and IgG ($P<0.001$), but higher D-dimer levels ($P<0.001$).

Conclusions: COVID-19 vaccination status and SARS-CoV-2 variant influence the inflammatory and immunologic response during SARS-CoV-2 infection, contributing to the severity of clinical presentation.

Keywords: COVID-19, vaccine, variants, inflammation, immunology, biomarkers

Ethical approval:

This study was conducted in accordance with the Declaration of Helsinki, and informed written consent was taken from study participants. Ethical approval was obtained from the Institutional Review Board of the Harvard T.H. Chan School of Public Health (Protocol No. IRB20-1425), the University Health Network Research Ethics Board (20-5775), the Institutional Research Ethics Committee of the Foundation for Medical Research (IREC No. FMR/IREC/C19/02/2020), the Institutional Review Board of Saifee Hospital (Project No. EC/008/2020) and the KEM Hospital Research Centre Ethics Committee (KEMHRC ID No. 2027).

Author contributions:

KKS, UP, WWF, KCK, YD, and NM conceptualized the study along with YM, SS, PD, GG and MW. KKS, YD, YM, SS, PD and GG were involved in data acquisition, and in study monitoring along with KCK, WWF, NM and UP. MW provided statistical expertise. KKS and UP analysed the data, KKS drafted the first draft of manuscript, and all authors reviewed and critically revised the draft and approved the final manuscript.

68 **Introduction**

69 COVID-19 infection is caused by the severe acute respiratory syndrome coronavirus 2 (SARS-
70 CoV-2), a major global health concern of the 21st century, and has affected more than 609
71 million people and caused over 6.5 million deaths worldwide.[1] The ability of SARS-CoV-2
72 viruses to undergo frequent and random mutations may result in the development of highly
73 contagious and lethal variants, and this has extended the COVID-19 pandemic through
74 multiple waves of infection.[1]

75 The progression of COVID-19 infection is associated with altered clinical manifestations and
76 changes in the level of related inflammatory and immunological biomarkers. Innate immune
77 responses, coagulation, and the initiation of pro-inflammatory responses are common
78 pathways to counteract infectious agents, which may result in increased circulating levels of
79 acute phase proteins such as C-reactive protein (CRP), ferritin, and D-Dimer. In particularly
80 acute cases, the proliferation of the virus in the host cell and its rapid spread in other cells
81 results in a cytokine storm, which is considered a critical condition.[2] The profile of human
82 immune response, transmission ability, laboratory characteristics, and antigenicity of the
83 virus depends at least partially on the COVID-19 virus variant.[3,4] While differences in
84 symptoms have been noted,[5] there are limited data available on inflammatory and
85 immunological responses to different SARS-CoV-2 variants, particularly from South Asian
86 populations.

87 Protective immunity through vaccines was paramount to reducing the severity of COVID-19
88 disease and breaking the chain of transmission. India also scaled up its domestic vaccine
89 research and development program for the launch of the vaccination drive in the country by
90 January 2021 and has achieved over 2 billion vaccinations so far.[6] Around 921 million

91 people had their first dose of the COVID-19 vaccine in India, 863 million were fully
92 vaccinated (2 doses), and around 139 million received their precautionary dose by
93 September 2022.[7] It has been observed that vaccination and its doses directly impact the
94 inflammatory and antibody response to SARS-CoV-2 infection.[8,9] However, evidence
95 regarding the effect of COVID-19 vaccination on the inflammatory and immunological
96 response among newly-infected patients remains limited, particularly from lower- and
97 middle-income populations such as those in South Asia.[10]

98 Few data have been reported on a comprehensive range of inflammatory and
99 immunological markers by COVID-19 vaccination doses and second versus third waves of
100 the COVID-19 pandemic (which roughly correspond to two distinct SARS-CoV-2 variants –
101 Delta and Omicron respectively) from COVID-19 patients, particularly in India. In this study,
102 we aimed to determine the association between COVID-19 vaccination doses and waves of
103 COVID-19, and a set of inflammatory and immunological biomarkers, among SARS-CoV-2-
104 infected patients in Maharashtra, India.

105

Materials and Methods

Study procedures

This analysis uses baseline data from a randomized controlled trial aiming to evaluate the effects of vitamin D and zinc supplementation on COVID-19 outcomes in Maharashtra, India (ClinicalTrials.gov registration: NCT04641195).[11] From April 2021 to February 2022, hospitalized or home-isolated COVID-19 patients aged ≥18 years with a positive RT-PCR or rapid antigen test and with mild to moderate symptoms were enrolled from two study sites: King Edward Memorial (KEM) Hospital and Research Centre, Pune, and Saifee Hospital, Mumbai.

Details regarding study procedures have been outlined previously,[11] baseline procedures are briefly described as follows. At enrolment, background information, medical history, and clinical symptoms were obtained and clinical assessment was conducted along with the collection of blood samples for routine laboratory investigations and study of specific inflammatory and immunological biomarkers. In addition, participants were asked about details of their COVID-19 vaccination status at baseline and during successive follow-ups. Routine blood investigation included testing of CRP, lactate dehydrogenase (LDH), serum ferritin, and D-dimer. This was performed at the respective hospital sites, which were accredited by the National Accreditation Board for Testing and Calibration Laboratories (NABL). All COVID-19 treatment, such as medications, was delivered by clinicians independently of the study, guided by the national treatment recommendations for COVID-19 at the time.[12]

Testing of other plasma biomarkers including angiopoietin-2 (Ang2), interleukin-6 (IL-6), soluble triggering receptor expressed on myeloid cells-1 (sTREM-1), immunoglobulin G (IgG),

129 and immunoglobulin M (IgM) were conducted at the coordinating institute, The Foundation
130 for Medical Research (FMR). Blood samples collected were processed at hospital sites for
131 plasma, and the centrifuged matrix was transported to FMR adhering to the transportation
132 regulations provided by the Government of India (GOI) for COVID-19 samples.[13] Aliquots of
133 plasma were prepared for further testing and stored at -20°C. The concentration of
134 biomarkers was quantified using sandwich enzyme-linked immunosorbent assay (ELISA),
135 was performed according to the manufacturer's instructions; Thermofisher Invitrogen, USA
136 (IL-6, Ang-2, sTREM-1) and RayBiotech, USA (IgG and IgM) and readings were observed at
137 450 nm. Due to issues with the sample kit, sTREM-1 assays were performed only for a
138 subset of 48 participants. To ensure accurate results, the samples were run in triplicates.

139 Variables of interest

140 Exposures of interest were COVID-19 vaccination status and wave during which the
141 participant was enrolled. Participants were categorized based on their COVID-19 vaccination
142 doses received till the day of enrolment. Participants with no COVID-19 vaccine were
143 grouped as unvaccinated, those with one dose were partially vaccinated, and those who
144 received second dose and/or the final third (precautionary or booster) dose were
145 categorized as fully vaccinated. Participants were enrolled across two waves of the COVID-
146 19 pandemic in India. These waves were defined as wave 2 (predominantly Delta; enrolled
147 from the start of the study in April 2021 to 15th December 2021), and wave 3
148 (predominantly Omicron; enrolled from 21st December 2021, onwards – no participants
149 were enrolled between 15th-21st December 2021).[14]

150 Outcomes of interest were the following inflammatory and immunological biomarkers:
151 serum CRP, LDH, and ferritin, plasma D dimer, IL-6, Ang2, sTREM-1, IgG, and IgM. As part of

152 the analysis, we considered other potentially important participant characteristics including
153 sex, age, education, health behaviour (smoking and alcohol consumption), pre-existing
154 medical conditions, COVID-19 medication, body mass index (BMI), COVID-19 vaccine type,
155 median number of days with symptoms and median days since last vaccine dose before
156 enrolment.

157 Statistical analysis

158 First, baseline demographic, clinical, health behaviour, COVID-19 medication, and
159 anthropometric characteristics were compared across the two exposures of interest: 1)
160 COVID-19 vaccination and 2) COVID-19 waves. Differences between groups were examined
161 by Pearson's Chi-squared tests or Fisher's exact tests (comparisons with cell counts <5) for
162 categorical variables, and Wilcoxon rank sum tests or Kruskal Wallis tests (comparisons
163 across >2 groups) for continuous variables. We also examined median biomarker levels
164 across the two exposures of interest, testing for differences across groups using Wilcoxon
165 rank sum tests or Kruskal Wallis tests, as described above.

166 Following this, effects of the exposures of interest on each outcome were modelled using
167 mixed-effects linear regression with robust standard errors. Models were adjusted for the
168 other exposure (either COVID-19 vaccination or wave), and for age, sex, health behaviour
169 (smoking and alcohol consumption), pre-existing medical conditions, COVID-19 medication,
170 BMI, COVID-19 vaccine type, and median number of days with symptoms and were
171 additionally adjusted for clustering at the hospital site level. Although we also initially
172 included days since last vaccination in regression models, this variable was dropped due to
173 collinearity with the COVID-19 vaccination variable. Missing observations for covariates

174 were minimal (maximum: 2 participants [1.1%] for any covariate) and we assumed these
175 were missing completely at random. We used the missing indicator method to handle
176 missing data in regression models. All analyses were performed using STATA, version 14.1
177 (StataCorp, Texas).

178 Ethics

179 The procedures followed in this study were in accordance with the ethical standards of all
180 responsible ethical committees listed below, and with the Declaration of Helsinki, and
181 informed written consent was taken from study participants. Ethical approval was obtained
182 from the Institutional Review Board of the Harvard T.H. Chan School of Public Health
183 (Protocol No. IRB20-1425), the University Health Network Research Ethics Board (20-5775),
184 the Institutional Research Ethics Committee of the Foundation for Medical Research (IREC
185 No. FMR/IREC/C19/02/2020), the Institutional Review Board of Saifee Hospital (Project No.
186 EC/008/2020) and the KEM Hospital Research Centre Ethics Committee (KEMHRC ID No.
187 2027). The trial is registered on ClincialTrials.gov: NCT04641195, and Clinical Trial Registry of
188 India (CTRI): CTRI/2021/04/032593. Health Ministry Steering Committee (HSMC) - GOI
189 endorsement was received before the commencement of the study.

Results

Overall baseline and clinical characteristics of the enrolled participants

Total 181 COVID-19 patients were included in the study. The mean (SD) age of the study participants was 47 (15.7) years, and the range was 18-87 years. One-fourth of participants (24.8%) were 60 years of age or older. The proportion of male participants was 51.3%, and 91.8% of participants had received secondary or higher-level education. Around 62% of participants were overweight or obese (30.9% in each category), only 6 individuals (3.3%) were underweight and a normal BMI was found in 34.8% participants. The median (interquartile range [IQR]) number of days with symptoms before enrolment was 3 days (2-4). 39.7% of participants reported comorbidities such as hypertension (24.8%), diabetes (20.9%), and cardiovascular disease (7.7%), and 19.8% of participants were on any COVID-19 medications. Among the antiviral medications, Remdesivir was used the most frequently (12.2%) (Table 1).

Baseline characteristics of the enrolled participants across exposure variables (vaccination status and waves of COVID-19 pandemic in India)

At the time of enrolment, one-fifth (19.9%) of individuals were unvaccinated, 13.3% had their first dose of COVID-19 vaccine, and 51.9% patients enrolled were fully vaccinated with two or three doses; 14.9% did not provide information on their vaccination status. The median days since last vaccine dose before enrolment was 126 days (IQR: 51-216). Fifty-eight percent individuals received COVISHIELD vaccine by AstraZeneca and Serum Institute of India, 7.1% received COVAXIN (Bharat Biotech) which was approved and introduced later, 19.9% were unvaccinated at the time of enrolment, and rest around 15% did not provide their vaccination details (Table 1).

213 A greater proportion of unvaccinated and fully vaccinated individuals was male (*P*=0.049).
214 Additionally, a greater proportion of partially vaccinated individuals was in 30-44 years age
215 group (*P*=0.008), had graduate education (*P*=0.006), was enrolled during the second wave
216 (*P*<0.001), and was using any COVID-19 medications (*P*=0.061). Full vaccination was
217 common in older participants who were more than 44 years, and among those who
218 reported hypertension (*P*=0.023), any pre-existing conditions, and obesity. The median days
219 from last dose before enrolment in partially vaccinated participants was 61 days (IQR: 31-
220 92) while it was 167 ([range 77-241] days for the fully vaccinated group (*P*<0.001]) (Table 1).

221 Most (66.3%) of the study participants were enrolled during the second wave. A larger
222 proportion of participants who enrolled in the second wave were aged 30-44 years
223 (*P*=0.381), and had normal BMI compared to third wave participants (*P*=0.019). All
224 participants enrolled in the third wave had secondary or higher education whereas about
225 one tenth of those enrolled in the second wave had primary or less education (*P*=0.004).
226 Close to half (46%) of participants enrolled in the third wave were obese, compared with
227 23.3% of participants enrolled in the second wave (Table 1).

228 **Levels of inflammatory and immunological biomarkers of COVID-19 infected participants**
229 **across vaccination status and waves of COVID-19 (unadjusted analyses)**

230 We first compared unadjusted median biomarker levels across vaccination status at
231 enrolment and the COVID-19 wave in which the participants were enrolled. The unadjusted
232 median CRP, LDH, ferritin, D-dimer and IL-6 levels were lower in fully and partially
233 vaccinated groups as compared to the unvaccinated group (*P*<0.001 for LDH and IL-6, and *P*=
234 0.005 for ferritin). The unadjusted levels of other inflammatory markers Ang-2 and sTREM-1
235 were higher in both vaccinated groups than unvaccinated group, but not significant

236 (*P*=0.454 and *P*=0.977 respectively). Unadjusted IgG levels were significantly elevated in
237 vaccinated groups as compared to the unvaccinated group especially in partially vaccinated
238 people (*P*=0.009), while unadjusted IgM levels were also notably high in partially vaccinated
239 group and lower in fully vaccinated people (*P*=0.014) (Table 2).

240 The study participants enrolled in the second wave had a higher median level of unadjusted
241 CRP, LDH, ferritin, and IL-6 compared to individuals enrolled in the third wave (*P*<0.05 for
242 all). These participants also had lower unadjusted median D-dimer levels, though this was
243 not significant (*P*=0.155). Furthermore, unadjusted plasma levels of IgM and IgG antibodies
244 were significantly lower in the third wave compared with second wave participants (*P*<0.001
245 and *P*=0.019 respectively) (Table 2).

246 **Regression analysis of effect of vaccination status and wave of COVID-19 pandemic on**
247 **inflammatory and immunological biomarkers (adjusted analyses)**

248 In fully-adjusted multivariable regression models, full vaccination (but not partial
249 vaccination) was associated with lower LDH and Ang-2; LDH (β: -77.4, 95% CI: -89.3 – -65.4,
250 *P*<0.001) and Ang-2 (β: -61.0, 95%CI: -121.0 – -1.0, *P*=0.046) respectively. Full vaccination
251 was also associated with lower D-dimer levels, but the association did not reach statistical
252 significance (β: -248.9, 95% CI:-1,009.4 – 511.7, *P*=0.521). Furthermore, partial and full
253 vaccination was associated with lower IL-6 levels as compared to no vaccination, with
254 similar magnitudes of difference for both groups but significant associations only for the
255 partially vaccinated group (β: -41.8, 95% CI: -81.7 – -1.9, *P*=0.040). In a subset of the cohort,
256 in fully vaccinated participants had higher sTREM-1 levels (β:72.6, 95% CI: 70.6–74.5,
257 *P*<0.001) (Table 3).

Although not significant, decreasing trends in CRP in partially vaccinated (β: -26.1, 95% CI: -102.1 – 50.0, *P*=0.502) and fully vaccinated individuals (β: -28.5, 95% CI: -88.0 – 30.9, *P*=0.347) were observed, similarly decreasing ferritin levels in partial and fully vaccinated participants were also noticed (β: -38.7, 95% CI: -439.6– 362.2, *P*=0.850 and β: -177.4, 95% CI: -691.3 – 336.5, *P*=0.499 respectively) (Table 3).

Significant associations between partial and full vaccination and elevated IgG were detected (β: 61.5, 95% CI: 48.9 – 74.1, *P*<0.001, and β: 62.2, 95% CI: 56.7 – 67.6, *P*<0.001 respectively). Estimates suggested increased levels of IgM associated with partial vaccination. However, these estimates of increase were not significant, and were also not statistically different from estimates for fully-vaccinated individuals, with fully overlapping confidence intervals (Table 3).

Additionally, in these fully-adjusted analyses, enrolment in the third wave was associated with significantly lower IL-6 (β: -12.0, 95% CI: -12.6 – -11.4, *P*<0.001), and CRP which was borderline significant (β: -21.7, 95% CI: -44.0 – 0.6, *P*= 0.056). On the other hand, higher D-dimer values were significantly associated with enrolment in third-wave (β: 322.5, 95% CI: 80.9 – 564.2, *P*=0.009). Other inflammatory markers including ferritin, LDH, and Ang-2 levels were also lower in third-wave versus second-wave participants, but differences in these biomarkers were not significant (Table 4).

Significant lower IgG and IgM were associated with enrolment in the third wave as compared to second-wave; IgM (β: -23.6, 95% CI: -42.3 – -4.9, *P*= 0.013) and IgG (β: -77.6, 95% CI: -99.4 – -55.8, *P*<0.001) (Table 4).

280 **Discussion**

281 In this study, we found that levels of inflammatory markers, particularly LDH and Ang-2
282 were significantly lower in fully vaccinated participants compared to unvaccinated
283 participants with COVID-19. Furthermore, we observed some evidence of lower IL-6 levels in
284 both partially and fully vaccinated participants, and substantially elevated IgG levels in both
285 partially and fully vaccinated participants. We also found that infection during the third
286 wave was associated with lower CRP, IL-6, and IgG levels, and higher D-Dimer levels.

287 Inflammation is a defence mechanism that is activated by a coordinated signalling pathway,
288 and also regulates inflammatory mediator levels in host tissue cells and inflammatory cells
289 recruited from the blood.[15] Previous studies have shown that vaccinated patients have
290 reduced severity of COVID-19 disease compared to unvaccinated patients, and individuals
291 with different vaccination doses have variable immune-inflammatory characteristics
292 including the existence of higher neutralizing antibodies response and lower inflammatory
293 markers.[16,17]

294 CRP LDH, ferritin, D-dimer, and IL-6 are inflammatory markers explored commonly in COVID-
295 19 and other research studies. However, evidence on the association between COVID-19
296 vaccination and variants and other inflammatory markers such as Ang-2 and sTREM-1, as
297 performed in our study, is scarce – we were unable to find any relevant studies during our
298 search of the literature on these associations. Some previous studies, including from South
299 Asia, have examined the relation between COVID-19 vaccination or variants and commonly
300 measured inflammatory and immunological markers.[10,18,19] Similar to our study, data from
301 these previous reports suggest generally inverse associations between vaccination against
302 COVID-19 and commonly measured inflammatory markers, and positive associations

303 between vaccination and immunological markers[10,18,19]. For example, an observational
304 study conducted in Pakistan on a cohort of 434 COVID-19 patients reported significantly
305 higher LDH, ferritin, and D-dimer levels in unvaccinated individuals compared to vaccinated
306 individuals.[18] In another study comparing unvaccinated COVID-19 patients with the fully
307 vaccinated group, significantly lower levels of IL-6 along with CRP and D-dimer were
308 reported in the fully vaccinated group. This study also showed noticeably higher IgG in fully
309 vaccinated individuals.[19] Similarly, significantly higher IgG levels among partially vaccinated
310 individuals were also observed in our study.

311 Also corroborating our results, a recent observational study conducted in India on 1160
312 hospitalized COVID-19 patients found similar trends of immunological and inflammatory
313 biomarkers. This included raised D-Dimer levels reported after the first vaccination, but
314 lower levels after 2 or 3 doses, and non-significant declining CRP.[10] Taken together with
315 these previous data, the lower CRP, LDH, ferritin, D-dimer, Ang-2, and IL-6 inflammatory
316 mediators among vaccinated individuals in our study add to the evidence that vaccine-
317 induced protection with higher immunological mediators may help to reduce inflammation,
318 which has been associated with more severe clinical outcomes in COVID-19.[20]

319 Previous evidence also suggests that the SARS-CoV-2 Omicron variant is less severe
320 compared to other variants, and limited data from previous reports suggest that the
321 Omicron variant may induce a smaller inflammatory and immune response.[8,21,22] The
322 possible reasons noted are less effective replication in the lung parenchyma,[23] and
323 sustained conservation of T-cell mediated immunity from previous infection or
324 vaccination.[24] A study conducted in Australia assessed severity of COVID-19 variants
325 through laboratory findings, and observed lower inflammatory markers, particularly ferritin,

326 LDH, and CRP levels, linked with Omicron variant compared to Delta variant. This study also
327 found no significant differences in D-dimer levels.[8] A recent comparative study of the three
328 waves of COVID-19 in India reported that infection with the Omicron variant versus Delta
329 variant was associated with significantly lower levels of CRP and IL-6.[21] Another study
330 conducted in Bangladesh reported higher levels of IgG, and higher risk of hospitalization and
331 oxygen support were associated with infection with the Delta compared to Omicron
332 variant.[22] Contributing to growing evidence suggesting that the Omicron variant is
333 associated with less severe disease, our study also suggests that participants enrolled in
334 waves of infection corresponding to the Omicron variant had lower inflammatory and
335 immunological biomarkers.

336 Contrary to other inflammatory biomarkers, D-dimer concentration in our study was
337 substantially higher in the third wave compared to the second wave participants. A study on
338 D-dimer levels suggested that early management of infection with steroids and
339 anticoagulants in the second wave may affect the production of D-dimer and limit the
340 endothelial damage, however, only a few participants were on steroids and anticoagulants
341 in our study.[25] Other reasons could be greater proportion of elderly individuals and high
342 BMI reported in the third wave in our study which are independent risk factors of high D-
343 dimer levels.[26,27] Importantly, we adjusted for these factors in analyses, suggesting that
344 other unmeasured clinical factors may underlie the observed associations.

345 The immune response is a dynamic process that might also change the inflammatory
346 parameters. Inflammatory response increases rapidly during the initial phase of infection
347 and falls during the recovery period, therefore, longitudinal changes in inflammatory
348 markers are more important rather than values of biomarkers at a single time point.[28]

349 Typically, after the onset of symptoms, immunological markers IgM and IgG can be detected
350 during the first week and at around two weeks respectively,[29] and gradually these
351 antibodies decline with time. The current study suggests that antibodies were higher among
352 vaccinated participants who later became ill with COVID-19 compared with unvaccinated
353 individuals. Particularly IgG antibodies remained high even after receiving two or three
354 vaccine doses compared to those who did not receive any vaccine doses. Together with
355 recent evidence from India indicating the effect of IgG levels on COVID-19-related measures
356 such as viral emission[30] these findings help characterize the biological effects of COVID-19
357 vaccination that may underlie disease severity and outcomes among SARS-CoV-2-infected
358 individuals.

359 This study has a few limitations. Information on prior COVID-19 infection was not collected
360 from the study participants which could affect in the vaccine-induced immune response and
361 its impact on inflammatory biomarkers. Secondly, different types of COVID-19 vaccines can
362 elicit diverse antibody responses, although in this study most (89%) of participants had
363 received the adenoviral vector vaccine (COVISHIELD) in comparison to the whole cell
364 inactivated virus (COVAXIN). Additionally, genome sequencing for confirmation of COVID-19
365 variants was not performed in this study, and classification of two waves of the COVID-19
366 pandemic was made based on defined time points by the federal COVID-19 task forces and
367 previous research articles.[14] Therefore, there is the possibility that participants enrolled at
368 beginning of the third wave may have been infected with either the Delta or the Omicron
369 variant of the SARS-CoV-2 virus. Analyses were based on a small sample size, particularly for
370 unvaccinated individuals in the third wave – which was likely due to good uptake of vaccines
371 during the study period. This may have limited our ability to detect associations in certain
372 cases, as evidenced by the wide confidence intervals for linear regression estimates.

373 Additionally, this study was based among individuals with mild-to-moderate COVID-19
374 symptoms and no severe outcomes, meaning that we were unable to clearly examine the
375 effect of vaccination status, wave of enrolment, and biomarker levels on clinical outcomes.

376 The foremost strength of this study is the diverse set of inflammatory and immunological
377 biomarkers of COVID-19 infection explored, which gives an opportunity to understand the
378 biological changes related to infection that are affected by prior COVID-19 vaccination and
379 by SARS-CoV-2 variants. Furthermore, we were able to account for a range of potential
380 demographic, clinical and health-related confounders by adjusting for these in final
381 regression models. Changes in trends cross unadjusted and adjusted analyses suggested the
382 importance of accounting for these characteristics when drawing conclusions regarding the
383 potential effect of vaccination status and COVID-19 wave on biomarker levels. Additionally,
384 this study also provides indicative data on the different clinical manifestations of two SARS-
385 CoV-2 variants of concern. The study setting in India enables applicability of findings to the
386 wider South Asia context where evidence on the effect of COVID-19 vaccine and SARS-CoV-2
387 variants on inflammatory and immunological responses to SARS-CoV-2 infection remains
388 scarce.

389 **Conclusion**

390 This study indicates that the inflammatory and immunologic response to SARS-CoV-2
391 infection may be least partly associated with prior COVID-19 vaccination status and with the
392 SARS-CoV-2 variant. This study provides data outlining potential pathways through which
393 COVID-19 vaccination may protect against, and SARS-CoV-2 variants may influence, the
394 likelihood of severe disease.

Unvaccinated: received no doses of COVID-19 vaccine. Partially vaccinated: received 1 dose of COVID-19 vaccine. Fully vaccinated: received 2 or 3 doses of COVID-19 vaccine.
IQR: interquartile range.
Unadjusted medians (IQR) are reported for all biomarkers (please refer to Tables 3 and 4 for adjusted analyses).
P values are based on Wilcoxon's rank sum test (2 groups), or Kruskal Wallis test (multiple groups).
The second wave of the COVID-19 pandemic in India was defined as the period spanning approximately April 2021 (when study enrolment began) to December 15th, 2021. The third wave was defined as the period spanning from December 21st, 2021, onwards.

498

Table 3. Estimates of association between COVID-19 vaccination status and inflammatory and immunological biomarkers.

	β Coefficient (95% Conf. Interval)	P
CRP (mg/L)		
Partially vaccinated	-26.1 (-102.1-50.0)	0.502
Fully Vaccinated	-28.5 (-88.0-30.9)	0.347
LDH (IU/L)		
Partially vaccinated	9.3 (-31.7-50.2)	0.658
Fully Vaccinated	-77.4 (-89.3--65.4)	<0.001
Serum Ferritin (ng/ml)		
Partially vaccinated	-38.7 (-439.6-362.2)	0.850
Fully Vaccinated	-177.4 (-691.3-336.5)	0.499
D-Dimer (ng/ml)		
Partially vaccinated	95.4 (-450.3-641.2)	0.732
Fully Vaccinated	-248.9 (-1,009.4-511.7)	0.521
IL-6 (pg/ml)		
Partially vaccinated	-41.8 (-81.7--1.9)	0.040
Fully Vaccinated	-36.3 (-81.4-8.9)	0.116
Angiopoietin-2 (pg/ml)		
Partially vaccinated	1.5 (-379.9-382.9)	0.994
Fully Vaccinated	-61.0 (-121.0--1.0)	0.046
sTREM-1 (pg/ml)		
Partially vaccinated	16.5 (-91.4-124.3)	0.765
Fully Vaccinated	72.6 (70.6-74.5)	<0.001
IgM (U/mL)		
Partially vaccinated	52.7 (-145.7-251.0)	0.603
Fully Vaccinated	-13.9 (-43.6-15.9)	0.360
IgG (U/mL)		
Partially vaccinated	61.5 (48.9-74.1)	<0.001
Fully Vaccinated	62.2 (56.7-67.6)	<0.001

Unvaccinated: received no doses of COVID-19 vaccine. Partially vaccinated: received 1 dose of COVID-19 vaccine. Fully vaccinated: received 2 or 3 doses of COVID-19 vaccine.
95% CI: 95% confidence interval.
Estimates based on mixed effect regression models with robust standard errors.
The comparison group in the model is unvaccinated participants.
The model is adjusted for wave enrolled, age, gender, type of vaccine, BMI, COVID medications, pre-existing diseases, days of symptoms, health behaviour (drinking and smoking), and clustered by hospital sites.

Table 4. Estimates of association between COVID -19 waves and inflammatory and immunological biomarkers.

	β Coefficient (95% Conf. Interval)	P
CRP (mg/L)		
Enrolled wave 3	-21.7 (-44.0-0.6)	0.056
LDH (IU/L)		
Enrolled wave 3	-14.4 (-30.8-1.9)	0.084
Serum ferritin (ng/ml)		
Enrolled wave 3	-29.1 (-171.1-112.9)	0.688
D-Dimer (ng/ml)		
Enrolled wave 3	322.5 (80.9-564.2)	0.009
IL-6 (pg/ml)		
Enrolled wave 3	-12.0 (-12.6--11.4)	<0.001
Angiopoietin-2 (pg/ml)		
Enrolled wave 3	-26.5 (-139.1-86.0)	0.644
sTREM-1 (pg/ml)		
Enrolled wave 3	--	--
IgM (U/mL)		
Enrolled wave 3	-23.6 (-42.3--4.9)	0.013
IgG (U/mL)		
Enrolled wave 3	-77.6 (-99.4--55.8)	<0.001

95% CI: 95% confidence interval.
Estimates based on mixed effects regression models with robust standard errors
The comparison group is wave 2 participants
The model is adjusted for age, gender, vaccination status (unvaccinated: 0 doses of COVID-19 vaccine, partially vaccinated: 1 dose, fully vaccinated: 2 or 3 doses) and type of vaccine, BMI, COVID medications, pre-existing diseases, days of symptoms, health behaviour (drinking and smoking), and clustered by hospital sites.
The second wave of the COVID-19 pandemic in India was defined as the period spanning approximately April 2021 (when study enrolment began) to December 15th, 2021. The third wave was defined as the period spanning from December 21st, 2021, onwards.
