ABSTRACT

BACKGROUND As of December 15, 2020, there have been been 71,351,695 confirmed cases of COVID-19 resulting in 1,612,372 deaths worldwide. Several vaccines are now available for emergency use, but it will take many months to immunize the world's population. There is a pressing need for out-patient treatment now.

METHODS We reviewed up-to-date information from several sources to identify potential treatments to be utilized now for COVID-19. We searched for all ongoing, completed and published trial results with subject numbers of 100 or more, and used a targeted search to find announcements of unpublished trial results.

RESULTS

As of December 15, 2020, we identified 750 trials currently in recruitment phase. Of these, 122 were directed at prevention in healthy individuals, 100 were classified as treatment of outpatients with documented infection, and 390 were for treatment of hospitalized inpatients. There were 9 trials focusing on the post discharge Tail phase. Among the trials, there were 60 vaccine trials, 120 trials of hydroxychloroquine, 33 trials of alternative therapy, 12 trials of colchicine, 38 trials of anticoagulants, 22 trials of the RNA polymerase inhibitor favipiravir (FVP), 19 trials of interferons, 18 trials of glucocorticoid, and 58 trials of plasma based products. Closure of enrollment was projected by the end of the year for 153 trials. We found 83 publications reporting findings in human studies on 14 classes of agents, and on 7 vaccines. There were 45 randomized or active controlled studies, the rest retrospective observational analyses. Most publications dealt with hospitalized patients, only 18 publications in out-

patients. Remdesivir, convalescent plasma, and synthetic anti-spike protein antibodies have been granted emergency use authorization in United States. There is also support for glucocorticoid treatment of the COVID-19 respiratory distress syndrome. There is data supporting the use of several antiviral medications, some of which are in use in other countries.

CONCLUSION. There is a need for antiviral agents in addition to mass immunization. It will be necessary for public health authorities to make hard decisions, with limited data, to prevent the continued spread of the disease and deaths.

Keywords: Coronavirus, COVID-19, SARS-Cov-2, remdesivir, hydroxychloroquine, favipiravir, iver-mectin

INTRODUCTION

SARS-Cov-2 spread with extraordinary speed from its origin in December 2019 in Wuhan, China. As of December 15, 2020, there have been 71,351,695 confirmed cases of COVID-19,resulting in 1,612,372 deaths worldwide affecting 220 countries and territories (1). Symptomatic COVID-19 exhibits a characteristic sequence of phases related to the primary viral attack, manifesting as an influenza-like illness. Then, in patients destined for severe disease, within seven to 10 days of onset of symptoms, an organizing pneumonia develops which requires assisted mechanical ventilation in up to 5% of patients (See Figure 1) (2,3). Elevated cytokines and a coagulopathy at this pulmonary stage suggests an immune reaction as probable cause (4,5).

In mainland China, vigorous efforts to contain the spread of COVID-19 by home isolation, closure of business activity, travel bans, and tracking and control of contacts succeeded. As of December 15, China has had 95,167 confirmed cases and 4,761 deaths, but the number of new cases has been low since April (1). Similar measures contained the epidemic in Taiwan and in New Zealand (1). However, the disease has not been controlled in the rest of the World, particularly Europe where there have been 22,116,845 cases with 487,632 deaths and the United States (USA) where, despite only a fifth of the population of China, there have been 16,041,095 confirmed cases of COVID-19 with 296,840 deaths. (1). In the Western World, as in China, the response to the pandemic was through reduction of person-to-person contact. Beginning in early March, social gatherings and meetings ended; schools and businesses were closed along with recreation areas, parks, and beaches. These social distancing efforts blunted the spread of the disease, but not with the results achieved in China. Due to economic pressures, epidemiologic containment was relaxed resulting in a significant ongoing surge well surpassing the original April peak.

The major industrialized countries have made an unprecedented effort to rapidly develop vaccines for COVID-19. Two mRNA vaccines have demonstrated 90% effectiveness at two months post immunization, and mass vaccination has begun. However, in view of the continuing daily increase in new cases and deaths, we believe that it is unwise to place sole reliance on immunization alone. Our goal was to assess the options at the present time for release of pharmacologic agents to treat and to prevent COVID-19 while pursuing widespread vaccination in 2021.

METHODS

CLINICAL TRIALS: We reviewed up-to-date information from multiple sources to identify potential treatments for COVID-19: The Reagan-Udall Expanded Access Navigator COVID-19 Treatment Hub was used to track the efforts of companies to develop therapeutic interventions. We searched for investigational trials in active recruitment and those that have completed enrollment. We used (A) covid-trials.org, a registry to collate all trials in real time with data pulled from the International Clinical Trials

Registry Platform and all major national registries (6). We cross validated information on (B) clinicaltrials.gov, the registry of clinical trials information maintained by the United States National Library of Medicine. We further cross referenced the trials on (C) the World Health Organization's International Clinical Trials Registry Platform (WHO ICTRP), and (D) (Cochrane COVID-19 Study Register. We excluded studies which were clearly observational with multiple different treatments, with no means of comparison. We further set a cutoff of 100 for numbers of subjects since smaller trial size typically lacks statistical power to enable regulatory approval. For each trial selected, we documented the setting of patient contact, either hospital or outpatient, the type of control procedure, the date the trial was initially registered, and the proposed date of completion of enrollment.

PUBLISHED TRIAL RESULTS: Our search was carried out on the week of December 7, 2020. We identified all publications on pubmed.gov to find peer reviewed articles, on medRxiv to find preprint reports and the WHO Global Literature on Coronavirus Disease. We further carried out daily Google™ searches on each potential treatment to find preliminary reports, typically presented as press releases, reviewed by a journalist. We included all publications in our results as well as trial results posted as complete on Clinicaltrials.gov. We did not exclude trials with less than 100 subjects, since many reports were interim, with trials ongoing.

VIRTUAL DISCUSSIONS AMONG CO-AUTHORS: We used the preprint server medRxiv to post a systematic analysis of the development of therapeutic interventions for COVID-19 in order to stimulate diffusion of the manuscript and allow widespread “open source” input from co-authors (7). Successive versions have been posted periodically as a chronicle beginning in late May, 2020 and continuing to date.

RESULTS

REVIEW OF CURRENT TRIALS: As of December 8, 2020, we identified 750 trials currently in recruitment phase with subject size of 100 or more. (Supplementary Table 1. Of these, 122 were directed at prevention in healthy individuals, 100 were classified as treatment of outpatients with documented infection, and 390 were for treatment of hospitalized inpatients. There were 9 trials focusing on the post discharge Tail phase. The remaining trials were unclear as to intended subjects. Among the trials, there were 60 vaccine trials, 120 trials of HCQ, 33 trials of alternative therapy, 12 trials of colchicine, 38 trials of anticoagulants, 22 trials of the RNA polymerase inhibitor favipiravir (FVP), 19 trials of interferons, 18 trials of glucocorticoid, and 58 trials of plasma based products. Closure of enrollment was projected by the end of the year for 153 trials.

COMPLETED TRIALS: As of December 8, 2020, there were 97 trials reporting completion with 100 or more subjects Supplementary Table 2). There were 52 trials in hospitalized patients, 9 directed at outpatients, and 12 prevention studies.

PUBLISHED RESULTS ON COVID-19 TRIALS: As of December 8, 2020 we found 83 publications reporting findings in human studies on 14 classes of agents, and on 7 vaccines (TABLE 1). There were 45 randomized or active controlled studies. The rest were retrospective observational analyses. Only 18 publications dealt with outpatient care, including 7 vaccine reports; the rest were all in hospitalized patients.

In the group of antiviral agents, the largest published randomized, controlled trials were with the intravenously administered RNA polymerase inhibitor remdesivir (8-11). A double blind, randomized placebo controlled trial of remdesivir, in 1062 moderate to severely ill patients was carried out by the National Institute of Allergy and Infectious Disease (NIAID) (9). The patients who received remdesivir had a median recovery time of 10 days (95% confidence interval [CI], 9 to 11), as compared with 15 days (95% CI, 13 to 18) among those who received placebo (rate ratio for recovery, 1.29; 95% CI, 1.12 to 1.49; P<0.001). P<0.001). The Kaplan-Meier estimates of mortality by 29 days after randomization were 11.4% with remdesivir and 15.2% with placebo (hazard ratio, 0.73; 95% CI, 0.52 to 1.03). On the basis of this trial, the Food and Drug Administration (FDA) approved the use of remdesivir for COVID-19 hospitalized patients. A different study of remdesivir in hospitalized patients with moderate COVID-19 clinical status showed improved clinical status by day 11 compared to standard of care for a 5 day course of remdesivir, but not for a 10 day course (11). There has been no data provided on viral clearance for the U.S. remdesivir studies. In early April, the WHO organized a megatrial, appropriately named Solidarity, to assess four separate treatment options in hospitalized patients: (a) Remdesivir, an intravenously administered inhibitor of RNA polymerase; (b) Lopanovir/Ritonavir (LPV/r; (c) LPV/r plus Interferon β-1a; and (d) the antimalarials hydroxychloroquine (HCQ) and chloroquine (12). Results of the Solidarity Trial were reported by the World Health Organization on October 15, 2020. They found no effect of remdesivir on 28 day mortality, need for mechanical ventilation nor duration of hospitalization in a study including 5451 hospitalized patients (12).

There were two positive randomized, active control clinical trials in China of the orally administered RNA polymerase inhibitor favipiravir (FVP) (13,14). In a trial comparing 116 patients on FVP to 120 on umifenovir, the 7 day clinical recovery rate was 55.9% for the umifenovir group and 71% in the FVP group (14). In Russia, a preliminary study of FVP showed reduced duration of viral shedding, and the drug was approved for clinical treatment beginning in multiple hospitals on June 12, 2020 (16). In a follow-up phase 3 study, they reported 27% clinical improvement at day 10 compared to 15% for standard care with 98% clearance of SARS-COV-2 compared to 79% (17). In India, a study of 150 mild to moderate COVID-19 patients showed median time to clinical cure of 3 days (95% CI: 3 days, 4 days) for FVP versus 5 days (95% CI: 4 days, 6 days) for control, P=0.030, and FVP was approved to treat COVID-19 in July (18). In late September, a report, still unpublished, of a randomized controlled study in Japan announced more rapid viral clearance in FVP treated patients.

There have been many studies of HCQ (19-46) (TABLE 1). A group in Marseille reported their experience with 3737 patients screened positive for SARS-Cov-2 and immediately treated with HCQ and azithromycin (AZM), after excluding patients at risk of QT prolongation (19). They showed clearance of viral shedding in 89.4% of the patients by ten days. The overall mortality in their population was 0.9%, none in patients under 60 years old, and no sudden cardiac deaths. They had no randomized control population, but their study prompted widespread use of HCQ throughout the world.

Subsequent randomized controlled studies in hospitalized patients have shown no clinical nor mortality benefit of HCQ. In the randomized RECOVERY trial in 1542 hospitalized patients in the United Kingdom, there was no significant difference in the primary endpoint of 28-day mortality (26.8% HCQ vs. 25% usual care; hazard ratio 1.09 [95% confidence interval 0.96-1.23]; p=0.18) (33). In the Solidarity Trial, there was no benefit of HCQ on mortality (HCQ RR=1.19 (0.89-1.59, p=0.23; 104/947 vs 84/906), need for mechanical ventilation, nor duration of hospitalization (12). However, in a retrospective comparison study at NYU Langone Health for all patients admitted between March 2 and April 5, 2020, there was a move to add zinc 100 mg daily to their standard HCQ plus AZM regimen (34). There was a significantly lower mortality (13.1%) among the zinc treated patients compared to those who did not receive zinc (22.8%).

There has been limited study of HCQ in outpatients. In one internet-based prevention study, with HCQ given for 5 days to healthy individuals with a significant exposure to SARS-Cov-2, the incidence of new illness compatible with COVID-19 did not differ significantly between participants receiving HCQ (49 of 414 [11.8%]) and those receiving placebo (58 of 407 [14.3%]); absolute difference −2.4 percentage points (95% confidence interval, −7.0 to 2.2; p=0.35) (35). The same group also treated 423 patients with mild symptoms imputed to COVID-19 (36). At 14 days, 24% (49 of 201) of participants receiving HCQ had ongoing symptoms compared with 30% (59 of 194) receiving placebo (p = 0.21).

A study in Spain of 293 patients with PCR-confirmed mild COVID-19, found no difference in viral load nor risk of hospitalization following 6 days HCQ treatment compared to untreated patients (37). The same group treated 1,116 healthy contacts of 672 Covid-19 index cases with HCQ while 1,198 were randomly allocated to usual care (38). There was no significant difference in the primary outcome of PCR-confirmed, symptomatic Covid-19 disease (6.2% usual care vs. 5.7% HCQ; risk ratio 0.89 [95% confidence interval 0.54-1.46]), nor evidence of prevention of SARS-CoV-2 transmission (17.8% usual care vs. 18.7% HCQ).

A large population study in Portugal surveyed all patients on chronic HCQ treatment and cross-verified against a mandatory database of patients registered with COVID-19 (39). The incidence of a positive PCR test for SARS-CoV-2 infection in patients receiving HCQ was 5.96%, compared to 7.45% in those not so treated, adjusted odds ratio 0.51 (0.37-0.70). However, two separate randomized controlled studies found no evidence of benefit of two months prophylactic treatment of hospital workers with HCQ (40, 41).

Published results with Lopanovir/ritonavir (LPV/r) have been disappointing (12, 42-44). In a randomized trial with 99 patients on LPV/r and 100 receiving standard care, there was no difference in time to clinical improvement, mortality nor viral clearance (43). In the RECOVERY trial in 1,596 hospitalized patients there was no significant difference in the primary endpoint of 28-day mortality (22.1% LPV/r vs. 21.3% usual care; relative risk 1.04 [95% confidence interval 0.91-1.18]; (p=0.58) (44). In the Solidarity Study, there was no effect of LPV/r on 28 day mortality LPV/r RR=1.00 (0.79-1.25, p=0.97; 148/1399 vs 146/1372), need for mechanical ventilation nor duration of hospitalization (12).

A possibly more favorable result was obtained in Hong Kong in a study of 86 patients assigned to triple combination therapy with LPV/r plus ribavirin plus interferon β-1 (45). Compared to a control group of 41 patients receiving LPV/r alone, the combination group had a significantly shorter median time from start of study treatment to negative SARS-Cov-2 nasopharyngeal swab (7 days [IQR 5–11]) than the control group (12 days [8–15]; hazard ratio 4.37 [95% CI 1.86–10.24], p=0•0010). The time to complete alleviation of symptoms was 4 days [IQR 3–8] in the combination group vs 8 days [7–9] in the control group; HR 3.92 [95% CI 1.66–9.23. This study was interpreted not as supporting LPV/r therapy, but rather focusing on interferon β-1 as the primary treatment modality.

In Cuba, a combination of interferon-α-2b and interferon λ on background therapy of LPV/r and chloroquine was successful in achieving viral clearance in 4 days in 78.6% of the patients compared to 40.6% of those receiving interferon-α-2b alone (48). In the Solidarity Study in hospitalized patients, there was no effect of injected interferon on 28 day mortality (IFN RR=1.16 (0.96-1.39, p=0.11; 243/2050 vs 216/2050), need for mechanical ventilation nor duration of hospitalization (12). However, a trial of nebulized interferon β-1 reported positive improvement in clinical status (51).

There have been many observational studies of immunomodulatory therapy with the IL-6 inhibitor tocilizumab and the IL-1 inhibitor anakinra to mitigate the pulmonary phase of COVID-19 which have suggested reduction of mortality and need for intubation in hospitalized severe and critically ill patients (27, 52-66). However, several randomized control studies have not been supportive (67-69); in the COVACTA trial, there was no benefit of tocilizumab in clinical status, mortality (19.7% tocilizumab vs placebo = 19.4%), nor in ventilator free days (68), and in the Cor-Immuno-Toci trial, no decrease in mortality at day 28 (69). The tocilizumab results in these randomized controlled trials were affected by a higher frequency of glucocorticoid use in the control groups.

Pre-COVID-19, glucocorticoid treatment had been a recognized treatment with mortality benefit for patients in severe respiratory distress (70). Dexamethasone has now demonstrated benefit in several COVID-19 hospital trials (70-72). In the RECOVERY trial, 2104 patients were randomly allocated to receive dexamethasone for ten days compared to 4321 patients concurrently allocated to usual care (72). Overall, 454 (21.6%) patients randomized to dexamethasone and 1065 (24.6%) patients receiving

usual care died within 28 days (age adjusted rate ratio [RR] 0.83; 95% confidence interval [CI] 0.74 to 0.92; p<0.001). Dexamethasone reduced deaths by one-third in the subgroup of patients receiving invasive mechanical ventilation (29.0% vs. 40.7%, RR 0.65 [95% CI 0.51 to 0.82]; p<0.001) and by one-fifth in patients receiving oxygen without invasive mechanical ventilation (21.5% vs. 25.0%, RR 0.80 [95% CI 0.70 to 0.92]; p=0.002), but did not reduce mortality in patients not receiving respiratory support at randomization (17.0% vs.13.2%, RR 1.22 [95% CI 0.93 to 1.61]; p=0.14). Most trials of other glucocorticoids have shown similar benefits in COVID-19 patients with acute respiratory failure (73-80)

There is also favorable data on convalescent plasma (81-87). A meta-analysis including 4173 patient outcomes across a multinational series of studies concluded that convalescent plasma treatment yielded a 57% reduction in mortality (85). The reduction was greatest in patients treated within 3 days of diagnosis with high titer antibody plasma. Based on evidence of safety in over 20,000 patients in an expanded access program coordinated by the Mayo Clinic, the U.S. FDA recently issued an emergency authorization for use of convalescent plasma (86). Monoclonal antibodies to the SARS-COV-2 spike protein have been synthesized. Treatment of ambulatory patients with the LY-CoV555 neutralizing antibody and the Regeneron combination of two antibodies early in the course of infection has shown success in reducing the frequency of hospitalization, and the FDA issued an emergency authorization for use in outpatients (88).

There have been a number of reports on agents not ordinarily considered as antivirals. These include famotidine, nitazoxanide, fluvoxamine, colchicine, and ivermectin (89-96). There have now been a number of trials including several randomized controlled studies suggesting benefit with ivermectin both in prevention and in treatment of COVID-19 (TABLE 1).

A number of vaccines have reported successful induction of neutralizing antibody and cellular immune responses in early phase trials (98-104). The Moderna and Pfizer Biontech mRNA spike protein vaccines released data showing over 90% effectiveness at preventing symptomatic infection in a 2 month post immunization observation period, and emergency authorization for immunization has been given.

DISCUSSION

SARS-Cov-2 overwhelmed medical preparedness for the pandemic. Current projections are for a continuation of new cases and deaths into 2021(105,106). Clinical trials to date have focused on hospitalized patients to try to prevent death. It is hoped that the use of remdesivir, convalescent plasma, glucocorticoids, anticoagulation and improved management of COVID-19 respiratory failure will lower the present rate of in hospital mortality which in some series has been as low as 6% but in most hospitals

still approaches 20% (76). However, it is essential to change the present dynamic of attempted therapeutic responses to recognize specific phases (107). In particular, efforts must now focus on prevention and treatment of the initial viral infection so that hospitalization can be avoided. We face a dilemma with inadequate current prevention and treatment for outpatients with mild to moderate disease, constituting 80% of the infected population and the primary mode of spread of SARS-Cov-2. The lessons learned in very sick hospitalized patients do not necessarily apply to the earlier viremic phase. Antiviral agents, such as remdesivir and favipiravir, interferon, convalescent plasma, and monoclonal antibodies are likely to be most effective during the early stage of viremia, which is pre-hospitalization.

Vaccines have been the sole hope held out by public health authorities to arrest SARS-Cov-2 in the early viremic phase. Progress on vaccine development has been rapid, but the speed of development does not reduce the challenges of developing a vaccine to be administered to the entire World population. Although neutralizing antibodies and memory T cells can be produced by the vaccine candidate, the demonstration of true protection requires long-term follow-up of an exposed vaccinated population. The current vaccines will be released for emergency use after only a two month period of observation. No matter how rapidly a vaccine advances to Phase III testing, the duration of follow-up cannot be shortened, and for SARS-Cov-2 possibly prolonged due to several factors. First, there is a risk of immune enhancement of infection which occurs when induced antibodies increase entry and internalization of virus into myeloid cells (108). This major complication struck the newly developed dengue vaccine in 2017 (109). Second, the sinister autoimmune pathogenicity of SARS-Cov-2 raises the risk of delayed long-term harm if the virus is not fully and immediately eradicated by the initial immune response to the vaccine. Furthermore, studies of recurrent coronavirus infections suggest that infection may confer immunity for less than a year (110). After implementation of a new vaccine, efforts to find volunteers for trials of new, more effective vaccines will be hampered if there is no treatment available for placebo treated patients who become infected. Vaccines are specific to the intended pathogen. There is the risk that the virus will mutate to a form for which the new vaccine may not be fully protective. It also follows that totally new viruses may emerge just as did SARS-Cov-2. COVID-19 is now the sixth severe viral epidemic to hit mankind in the past 20 years; certainly it has been more widespread than SARS-Cov-1, H1N1 influenza, MERS, Zika and Ebola, but that does not diminish the significance of these prior viral epidemics. Development of antigen specific vaccines takes a long time during which disease takes a large toll as has been the case for SARS-Cov-2. The succession of viral afflictions points to the need to implement widespread use of effective antiviral agents.

There is a need for therapeutic interventions which can be used to treat all outpatients with positive COVID-19 tests at the time of initial symptoms, not waiting for deterioration requiring hospital care. Remdesivir administered intravenously for five days is not a practical daily outpatient treatment; Gilead© is attempting to develop an inhaled remdesivir formulation, but those efforts are only now beginning. Favipiravir, a tablet, could be used in early stages of infection and has now been released in Russia, Hungary, and in India, but not in the United States and the European Union. It has known embryogenic risks, so its use requires restrictions on women of childbearing potential, as is the case with tretinoin for acne and thalidomide for multiple myeloma. Trials with camostat, the serine protease inhibitor, capable of blocking cell entry of SARS-Cov-2, are not due to end till the fourth quarter of the year.

Similarly, a prevention trial with colchicine is not scheduled to end until the fourth quarter of 2020. Convalescent plasma has supportive data but is only currently used in the inpatient setting. Monoclonal antiviral neutralizing antibodies based on the same principle have finally received emergency use authorization for ambulatory patients. However, the scale of production of these monoclonal antibodies is too limited to offer to all who need this treatment. Interferon formulations have shown promise in several studies. There have been several randomized control studies suggesting benefit with ivermectin.

Yet, at this time, no outpatient therapy has been proven safe and effective in large scale phase III randomized, placebo-controlled studies. There are strong arguments to avoid emergency use of agents until trials are completed and analyzed, but the agents suggested are not new. Most are drugs like ivermectin, colchicine, and the interferons, marketed and available for other conditions and with well-known safety profiles. There is a clear need to offer outpatient therapeutic intervention now to the world's population.

There is a precedent to resolve the conflict between immediate clinical need and the requirements for rigorous controlled trials to prove efficacy. We should remember that the greatest success in fighting a pandemic occurred over the past two decades in the battle against the HIV virus which causes AIDS. AIDS was first recognized in 1981 in the MSM (men who have sex with men) community (111). The disease was considered a death sentence. There was widespread fear because there was no treatment, and projections of infection escalated into the millions. The first AIDS remedy was azidothymidine (AZT), synthesized in 1964 in the hope that it would combat cancer. Twenty years later Dr. Samuel Broder, head of the National Cancer Institute, showed that the drug had activity against the HIV virus in vitro (112). Burroughs Wellcome launched a rapidly conceived trial with just 300 patients. They stopped the trial in 16 weeks claiming that more patients survived on AZT. The FDA came under enormous pressure from AIDS activists to make the drug available, and it was approved on March 19, 1987, with only that one trial. It had taken 20 months for the FDA to give approval to release the drug. To this day, the design and results of the trial remain controversial.

The LGBT community continued to battle for early release of other medications to combat the AIDS pandemic. On October 11, 1988, a massive protest occurred at the FDA. It was back then Dr. Anthony Fauci who publicly advanced the idea of a parallel track to make drugs widely available even while studies are progressing: "Clearly, the standard approach to the design of clinical trials—that is, rigid eligibility criteria as well as the strict regulatory aspects that attend clinical trial investigations and drug approval—was not well-suited to a novel, largely fatal disease such as this with no effective treatments, and we had many intense discussions about how to make that approach more flexible and ethically sound. One example, which I and others worked closely with the AIDS activists to develop, was called a parallel track for clinical trials. The parallel track concept, which the United States Food and Drug Administration ultimately came to support, meant that there would be the standard type of highly controlled admission criteria and data collection for the clinical trial of a particular drug. In parallel, however, the drug also could be made available to those who did not meet the trial's strict admission

criteria but were still in dire need of any potentially effective intervention, however unproven, for this deadly disease" (113).

The parallel track advocated by Dr. Fauci was adopted. Today, there are 41 drugs or combinations approved by the FDA to treat and to prevent HIV infection. There is still no vaccine. There are now an estimated 1.1 million patients with HIV in the United States, most enjoying near normal life expectancy thanks to the antiviral agents. The CDC has contributed greatly to limit the spread of HIV by advocating safe sex practices, but social distancing is not the norm for HIV. Rather "treatment as prevention" for people with HIV using highly active antiretroviral regimens to prevent transmission as well as pre-exposure prophylaxis with a daily antiviral combination pill are currently endorsed by the CDC and adopted in wide segments of the at risk population (114).

In this pandemic crisis, we appeal to public health authorities to change the dynamic of current studies to outpatient care and to cross institutional, commercial and international boundaries to collate and combine all randomized controlled data submitted for all agents in Europe, China, Russia, Japan, India and other countries, and by competing companies, whether officially published, posted on line, or unpublished to finalize confirmatory results. The Solidarity Trial is a model of what could and should be done to unify a worldwide effort to pursue randomized controlled studies in outpatients. At the same time, agents with favorable preliminary results and no safety issues should be made available immediately through a parallel track. In Russia and India, the parallel track has been fully implemented, with FVP now offered as treatment throughout both countries, even as further confirmatory controlled trials proceed. It is perfectly reasonable to authorize emergency vaccination. However, it is unwise to rely solely on the hope for eventual mass vaccination to stop SARS-Cov2. Antiviral medication has succeeded in limiting HIV, and antivirals are just as important as annual vaccination for control of influenza. It is necessary for public health authorities to make hard decisions now despite limited current data and offer outpatient treatments on a broad front with no further delay.

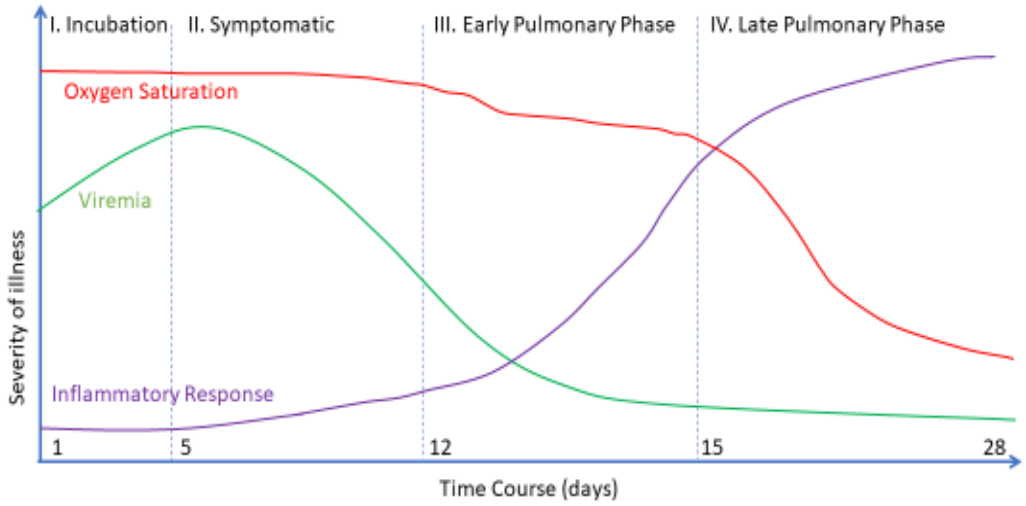

Figure 1: THE PHASES OF COVID-19 INFECTION. Asymptomatic viremia typically lasts for 5 days followed by symptoms of an upper respiratory infection. The immune response takes hold over the next week. Pneumonic infiltrates begin to appear. In patients destined for severe infection, a hyperinflammatory reaction takes hold, leading to worsening of pulmonary symptoms, hypoxia, and potentially acute respiratory distress syndrome.

TABLE 1. PUBLISHED STUDIES AS OF DECEMBER 10, 2020. Each agent is listed along with the country originating the publication. We have listed studies with 100 or more subjects. The type of control procedure: RCT: Randomized controlled study PLAC: Placebo , soc: standard of care which is variable depending on each location. AC: Active control: the control options are listed in parenthesis. OBS: retrospective observation study. LPV/R: lopanovir/ritonavir; HCQ: hydroxychloroquine; AZM: azithromycin; IFN: interferon; tocilizumab: TCZ. SEV: severe; CRIT: critical; MOD: moderate. W.H.O.: World Health Organization

TREATMENT	LOCATION	TYPE OF CONTROL	NUMBER SUBJECTS	SETTING	SEVERITY	RESULTS
Remdesivir[8]	China	RCTPLAC vs soc	273	HOSP	SEV	mortality in remdesivir group 14%, control 13% 11% in remdesivir group with <10 days symptoms Vs 14% in placebo group, no difference in viral clearance
Remdesivir[9]	U.S.A.	RCTPLAC	1062	HOSP	SEV,CRIT	29 day mortality 11.4% with remdesivir and 15.2% with placebo by day 29 (hazard ratio, 0.73; 95% CI, 0.52 to 1.03)
Remdesivir[10]	U.S.A.	AC(5 day vs 10 day, no control)	397	HOSP	MOD,SEV	10 day group had more severe disease, mortality 8% in 5 day group 11% in 10 day group
Remdesivir[11]	U.S.A.	AC(5 day vs 10 day, vs soc)	596	HOSP	MOD	Improved clinical status in 5 day group but not in 10 day group
Remdesivir[12]	W.H.O.	AC(10 day, vs soc)	5451	HOSP	MOD,SEV	Mortality Remdesivir RR=0.95 (0.81-1.11, p=0.50 301/2743 active vs 303/2708 control
FVP[14]	China	AC (umifenovir vs favipiravir)	240	HOSP	MOD,SEV	Clinical recovery rate 56%umifenovir vs 71% fvp

						time to fever reduction and cough shorter fvp
FVP[15]	Japan	OBS (no control)	1918	HOSP	MOD,SEV,CRIT	Mortality 11.6% at one month
FVP[17]	Russia	AC (FVP vs soc)	196	HOSP	MOD	By day 10 Clinical Improvement 27% FVP vs 15% soc , 98% neg PCR vs 79%
FVP[18]	India	AC (FVP vs soc)	150	HOSP	MOD	median time to clinical cure of 3 days (95% CI: 3 days, 4 days) for FVP versus5 days (95% CI: 4 days, 6 days) for control, P=0.030
HCQ[19]	France	OBS(hcq+azm, noncomparable control group)	3737	MIXED	MILD,MOD	0.9% overall mortality, no sudden death, no cardiac arrythmias
HCQ[22]	China	RCT(hcq vs soc)	150	HOSP	MILD,MOD	No difference in viral clearance at 28 days
HCQ[23]	U.S.A.	OBS(hcq vs no hcq)	338	HOSP	MOD,SEV	Mortality twice as high in patients chosen for HCQ treatment
HCQ[24]	U.S.A.	OBS (hcq vs no hcq)	1376	HOSP	MOD,SEV	no significant association between HCQ use and intubation or death (hazard ratio, 1.04, 95% confidence interval, 0.82 to 1.32). HCQ treated patients were sicker with ppO2 223 vs 360 for controls still lower than controls after propensity score matching 223 vs 273

HCQ[25]	U.S.A.	OBS (hcq+azt vs hcq vs azt)	1438	HOSP	MOD,SEV	Overall in-hospital mortality was 20.3%,25.7% hcq+azt, 19.9% hcq alone neither drug 17.7%, cardiac arrest more likely with hcq+azt
HCQ[26]	France	OBS (hcq vs no hcq)	181	HOSP	MOD,SEV	no difference in mortality or need to transfer to ICU
HCQ[27]	U.S.A.	OBS (hcq vs hcq plus azm, azm	2512	HOSP	MOD,SEV	30-day unadjusted mortality for patients receiving hydroxychloroquine alone, azithromycin alone, the combination or neither drug was 25%, 20%, 18%, and 20%,
HCQ[28]	U.S.A.	OBS (hcq vs hcq plus azm, azm	2541	HOSP	MOD,SEV	Overall mortality was 18.1% (95% CI:16.6%-19.7%); by treatment: hcq+azt, (20.1% [95% CI: 17.3%-23.0%]), hcq alone, (13.5% [95% CI: 11.6%-15.5%]), azt alone,(22.4% [95% CI: 16.0%-30.1%]), neither drug, (26.4% [95% CI: 22.2%-31.0%]).
HCQ[29]	Brazil	RCT (hcq, hcq+azm vs soc)	504	HOSP	SEV	Clinical status at 15 days no different with hcq, hcq+azm, soc
HCQ[30]	Brazil	RCT (azm vs soc)	397	HOSP	SEV	primary endpoint was not significantly different between the azithromycin and control groups (OR 1·36 [95% CI 0·94–1·97], p=0·11)
Chloroquine[31]	Brazil	RCT (Chloroquine high dose to low dose)	121	HOSP	MOD,SEV	No difference in viral clearance, higher mortality in high dose group

HCQ[32]	U.S.A.	RCT (HCQ vs soc)	479	HOSP	MOD,SEV	Mortality 28 days 10.4% HCQ, 10.6% soc
HCQ[33]	U.K.	RCT (HCQ vs soc)	1542	HOSP	MOD,SEV	no significant difference in28-day mortality (26.8% hydroxychloroquine vs. 25% usual care; hazard ratio 1.09 [95% confidence interval 0.96-1.23]; p=0.18) (Mortality RR=1.19 (0.89-1.59, p=0.23; 104/947 HCQ vs 84/906 control
HCQ[12]	W.H.O.	AC(HCQ vs soc)	1853	HOSP	MOD, SEV	Mortality RR=1.19 (0.89-1.59, p=0.23; 104/947 HCQ vs 84/906 control
HCQ[34]	U.S.A.	OBS (hcq+azm +zinc vs hzq +azm)	932	HOSP	MOD,SEV	Reduction in mortality with addition of zinc OR 0.449, 95% CI 0.271-0.744).
HCQ[35]	U.S.A.	RCTPLAC	821	OUTPAT	HEALTHY	No significant difference in incidence of subsequent COVID-19 infection (11.8% HCQ, 14.3% PLAC, p=0.35)
HCQ[36]	U.S.A.	RCTPLAC	423	OUTPAT	MILD	At 14 days, 24% (49 of 201) of participants receiving hydroxychloroquine had ongoing symptoms compared with 30% (59 of 194) receiving placebo (P = 0.21)
HCQ[37]	Spain	RCTPLAC	293	OUTPAT	MILD	no difference in viral load at 7 days after 6 days HCQ treatment nor risk of hospitalization compared to untreated patients

HCQ[38]	Spain	RCTPLAC	2324	OUTPAT	HEALTHY	no significant difference in the primary outcome of PCR-confirmed, symptomatic Covid-19 disease (6.2% usual care vs. 5.7% HCQ; risk ratio 0.89 [95% confidence interval 0.54-1.46]), nor evidence of prevention of SARS-CoV-2 transmission (17.8% usual care vs. 18.7% HCQ)
HCQ[39]	Portugal	OBS(HCQ vs no HCQ)	1293	OUTPAT	HEALTHY	odds ratio of SARS-CoV-2 infection for chronic treatment with HCQ 0.51 (0.37-0.70).
HCQ[40]	U.S.A.	RCTPLAC	132	OUTPAT	HEALTHY	2 month treatment with HCQ in hospital workers no significant difference in SARS-Cov-2 infection rate HCQ 6.3% vs placebo 6.6%
HCQ[41]	Canada	RCTPLAC	1483	OUTPAT	HEALTHY	3month treatment with HCQ in hospital workers no significant difference in SARS-Cov-2 infection rate HCQ 0.27 events per person/year vs placebo 0.38% (p=0.18)
LPV/r[43]	China	RCT(soc)	199	HOSP	SEV	No differences in mortality, viral load; time to clinical improvement 1 day less in lpv/r group
LPV/r[44]	U.K.	RCT(soc)	1596	HOSP	MOD,SEV	no significant difference in the primary endpoint of 28-day mortality (22.1% LPV/r vs. 21.3% usual care; relative risk 1.04 [95% confidence interval 0.91-1.18];(p=0.58)
LPV/r[12]	W.H.O.	AC(LPV/r vs soc)	2771	HOSP	MOD,SEV	Mortality LPV/r (RR=1.00 (0.79-1.25, p=0.97; 148/1399 vs 146/1372

LPV/r[45]	Hong Kong	AC(lpv/r+ribavirin+beta interferon vs lpv/r+ribavirin)	127	HOSP	MOD.SEV	Triple combination of interferon beta-1b, lpv/r, and ribavirin yielded more rapid viral clearance but attributable primarily to interferon
IFN- β-1a[46]	Cuba	OBS	761	HOSP	MIXED	Case fatality ratio 0.92 for interferon treated patients
IFN[12]	W.H.O.	AC(vs soc)	4100	HOSP	MOD,SEV	Mortality IFNRR=1.16 (0.96-1.39, p=0.11; 243/2050 vs 216/2050)
IFN-α nasal drops[50]	China	OBS	2944	OUTPAT	HEALTHY	No cases of COVID-19 compared to historical control
IFN- β-1a(nebulized)[51]	U.K.	RCT(soc)	101	HOSP	MOD,SEV	OR for clinical improvement 2·32 (1·07–5·04)
TCZ[32]	U.S.A.	OBS (TCZ vs soc)	547	HOSP	CRIT	30 day unadjusted mortality with and without TCZ of 46% versus 56%
TCZ[57]	U.S.A.	OBS (TCZ vs soc)	154	HOSP	CRIT	TCZ was associated with a 45% reduction in hazard of death [hazard ratio 0.55 (95% CI 0.33, 0.90)]
TCZ[58]	France	Matched cohort (TCZ vs soc)	168	HOSP	SEV	TCZ was associated with a 51% reduction in composite of death and mechanical ventilation(HR)=0.49 (95% confidence interval (95CI)=0.3-0.81), p-value=0.005)

TCZ[59]	Spain	OBS	1229	HOSP	SEV	TCZ associated with decreased risk of death (aHR 0.34, 95% CI 0.16 to 0.72, p=0.005) and ICU admission or death (aHR 0.38, 95% CI 0.19 to 0.81, p=0.011) among patients with baseline CRP >150 mg/L,
TCZ[60]	U.S.A.	OBS (TCZ early vs late treatment))	154	HOSP	CRIT	increased survival and avoidance mechanical ventilation with early treatment
TCZ[61]	Italy	OBS	1221	HOSP	SEV	15.6% moratility at 14 days, 20% at 30 days in TCZ treated patients
TCZ[62]	Spain	OBS(TCZ vs soc)	171	HOSP	MOD,SEV	TCZ associated with decreased risk OF ICU admission (10.3% vs. 27.6%, P= 0.005) and need of invasive ventilation (0 vs 13.8%, P=0.001)
TCZ[63]	Italy	OBS(TCZ vs soc)	544	HOSP	SEV	TCZ treatment was associated with a reduced risk of invasive mechanical ventilation or death (adjusted hazard ratio 0·61, 95% CI 0·40–0·92; p=0·020).
Anakinra[66] .	Greece	OBS(vs soc)	130	HOSP	SEV	Incidence of severe respiratory failure 22% anakinra patients vs 59% soc,, 30 day mortality 11.5% anakinra vs 22.3% soc).
TCZ[68]	U.S.A.	RCTPLAC(TCZvs soc)	452	HOSP	SEV,CRIT	No difference in mortality day 28(19.7% TCZ, 19.4% PLAC)

TCZ[69]	France	RCT(TCZ vs soc)	130	HOSP	SEV	HR for mechanical ventilation or death at day 14 0.58 (90% CrI, 0.30 to 1.09). day 28 mortality 11.1% TCZ, 11.9% soc (adjusted HR, 0.92; 95% CI 0.33-2.53).
Dexamethasone[71]	Brazil	RCT (soc)	299	HOSP	MOD,SEV	Dexamethasone increased ventilator free days from 4.0 to 6.6, no difference in 28 day mortality
Dexamethasone[72]	U.K.	RCT(soc)	6119	HOSP	MOD,SEV	Dexamethasone reduced 28-day mortality by 35% in patients receiving invasive mechanical ventilation (rate ratio 0.65 [95% CI 0.51 to 0.82]; p<0.001) and by 20% in patients receiving oxygen without invasive mechanical ventilation (rate ratio 0.80 [95% CI 0.70 to 0.92]; p=0.002
Methylprednisolone[73]	Italy	RCT(soc)	173	HOSP	SEV	Mehtylprednisolone group had fewer deaths (6 vs. 21, adjusted HR=0.29; 95% CI: 0.12-0.73) and more days off invasive MV (24.0 plus-or-minus sign 9.0 vs. 17.5 plus-or-minus sign 12.8; p=0.001)
Methylprednisolone[74]	U.S.A.	OBS(soc)	213	HOSP	SEV	Early short course of methylprednisolone resulted in decrease need for ICU care, mechanical ventilation and mortality ((34.9% vs 54.3%, P = .005)
Methylprednisolone[78]	Brazil	RCT(soc)	393	HOSP	MOD,SEV	Overall 28-day mortality was 76/199 (38.2%) in the placebo group vs 72/194 (37.1%) in group which received methylprednisolone short 5 day course (P=0.629)

Hydrocortisone[79]	France	RCT(soc)	149	HOSP	CRIT	Treatment failure in hydrocortisone group 42% vs 51% placebo
Hydrocortisone[80]	U.S.A.	RCT(soc)	403	HOSP	SEV	90% probability of superiority of hydrocortisone in organ support free days. No mortality difference
Convalescent plasma[81]	China	RCT(soc)	103	HOSP	SEV.CRIT	time to clinical improvement at 28 days was 4.9 days shorter (95% CI, −9.33 to −0.54 days) in convalescent plasma group (HR, 2.15 [95% CI, 1.07-4.32]; P = .03). No significant difference in critically ill patients. Mortality 28-day mortality (15.7% convalescent plasma vs 24.0% control ; P = .30)
Convalescent plasma[82]	U.S.A.	Matched cohort study	241	HOSP	SEV	No significant difference mortality or rate hospital discharge
Convalescent plasma[85]	U.S.A.	OBS	3,082	HOSP	MOD,SEV	adjusted 30-35 day mortality was 30% in patients treated with plasma with low antibody levels (IgG) 35 or more days after COVID-19 diagnosis. By contrast 30-day mortality was 20% in 353 patients treated within 3 days of diagnosis with plasma with high antibody levels.
Convalescent plasma[86]	U.S.A.	OBS	21,987	HOSP	MOD,SEV	7 day mortality 13%

Convalescent plasma[87]	India	RCT(soc)	464	HOSP	MOD, SEV	Progression to severe disease or all cause mortality at 28 days after enrollment occurred in 44 (19%) participants in the intervention arm and 41 (18%) in the control arm (risk difference 0.008 (95% confidence interval −0.062 to 0.078); risk ratio 1.04, 95% confidence interval 0.71 to 1.54).
LY-CoV555[88]	U.S.A.	RCT(soc)	452	OUTPAT	MILD,MOD	6.2% of patients receiving placebo had emergency room visit or hospitalization vs 1.6% patients who received antibody
Famotidine[89]	U.S.A.	OBS(famotidine vs soc)	1620	HOSP	MOD,SEV	HR for famotidine for death or intubation 0.43, 95% CI (0.21-0.88)
Nitazoxanide[90]	Brazil	RCTPLAC(Nitazoxanide vs plac)	392	OUTPAT	MILD	Art one week, 78% complete resolution symptoms in the nitazoxanide arm and 57% in the placebo arm (p=0.048). viral clearance in 29.9% of patients in the nitazoxanide arm versus 18.2% in the placebo arm (p=0.009).)
Fluvoxamine[91]	U.S.A.	RCT(fluvoxamine vs soc)	152	OUTPAT	MILD,MOD	Clinical deterioration in 0 patients on fluvoxamine, 8.7% placebo (p<0.009)
Ivermectin[92]	U.S.A.	OBS(ivermectin vs soc)	280	HOSP	MOD,SEV	lower mortality in the ivermectin group (25.2% versus 15.0%, OR 0.52, 95% CI 0.29-0.96, P=.03)
Ivermectin[93]	India	Case Control (Ivermectin vs placebo)	115	OUTPAT	HEALTHY	Two doses of ivermectin yielded 73% reduction in COVID_9 cases
Ivermectin[94]	Bangladesh	OBS(ivermectin vs soc)	248	HOSP	MOD,SEV	Mortality 0.9% ivermectin vs 6.8% control

Ivermectin[95]	Egypt	RCT(ivermectin vs soc)	304	OUTPAT	HEALTHY	7.4% developed COVID symptoms ivermectin vs 58.4%% control
Mesenchymal Stem Cells [97]	China	RCTPLAC	101	HOSP	SEV WITH LUNG DAMAGE	Lesion volume decreased compared to placebo ($p<0.05$)
ChAdOx1-nCoV19[98]	U.K.	RCT (plac)	1077	OUTPAT	HEALTHY	100% spike protein neutralising antibody, spike specific T cell responses
mRNA1273[99]	U.S.A.	RCT(plac)	45	OUTPAT	HEALTHY	High neutralising antibody titiers, positive Th1-CD4 response
Ad5 vectored Covid Vaccine[100]	China	RCT(plac)	603	OUTPAT	HEALTHY	Significant neutralizing antibody titers and positive T cell response
NVX-Cov2373[101]	Australia	RCT(plac)	134	OUTPAT	HEALTHY	Significant neutralizing antibody titers and positive T cell response
Coronavac[102]	China	RCT(plac)	330	OUTPAT	HEALTHY	Significant neutralizing antibody titers and positive T cell response
Ad5 and Ad26 vectored Covid Vaccines[103]	Russia	OBS	76	OUTPAT	HEALTHY	Significant neutralizing antibody titers and positive T cell response
BTN162b1 and b2[104]	U.S.A.	RCT(plac)	195	OUTPAT	HEALTHY	high titer, broad serum neutralizing responses, TH1 phenotype CD4+ T helper cell responses, and strong interferon γ (IFNγ) and interleukin-2 (IL-2) producing CD8+ cytotoxic T-cell responses
