ABSTRACT

We analyzed available mpox cases reports in Sierra Leone from January to June 2025 following a historic increase in mpox cases across multiple urban and rural regions in the country. Here, we assessed demographic and clinical data from 187 case reports. Mpox case reports in this study were primarily from Bo (86/187; 46.0%) and Freetown (48/124; 25.7%). Most case reports were from male patients (101/187; 54.0%) as compared to females (86/187; 46.0%), with an overall median age of 26 years (IQR 22-34). The median age was higher among males (30 years; IQR 25-39) then females (24 years; IQR 21-27). Rash, fever, headache, lesions, and generalized pain were reported for all patients, where data was reported. Lymphadenopathy, muscle pain, sore throat, and cough were reported less commonly. Age- and sex-specific interventions, as well as community engagement that includes historically stigmatized groups are critical for mpox containment and mitigation measures in Sierra Leone.

Keywords: mpox; mpox virus; Sierra Leone; demographics; outbreak; epidemiology; clinical characteristics

INTRODUCTION

Mpox is an emerging zoonotic viral disease caused by mpox virus (also known as monkeypox virus; MPXV) endemic in tropical forest regions of Central and Western Africa [1, 2]. Human mpox was first identified in the Democratic Republic of the Congo (DRC) in 1970 with subsequent infections identified in multiple West African countries from 1970-1971 [3-5]. Historically, MPXV was described by two genetically, clinically, and geographically distinct clades, Clade I and Clade II, which are endemic in tropical, forested regions of Central Africa and Western Africa, respectively [1, 2]. Clades I and II have been subdivided into two subclades – a and b. The emergence of subclades Ib and IIb have been associated altered clinical and epidemiological characteristics, extensive APOBEC3 mutations, and rapid geographic expansion due to sustained human-to-human transmissions, including within dense sexual networks [6-8]. Rapid global expansion of Clade IIb MPXV in 2022 resulted in >91,000 confirmed infections in non-endemic regions and the declaration of the first public health emergency of international concern for mpox by the World Health Organization (WHO) [7, 9]. A second mpox PHEIC associated with Clade I MPXV was declared in 2024 and is currently ongoing [10].

Prior to 2022, knowledge regarding mpox morbidity and mortality were largely driven based on data from Clade I MPXV infections in Central Africa. Historically, the Democratic Republic of the Congo has faced the greatest public health impacts from mpox among all endemic and non-endemic regions, with the highest morbidity and mortality found among children <5 years [11, 12]. The extent of Clade II MPXV circulation among regions in West Africa is largely unknown though the circulation of subclades IIa and IIb correspond to regions east and west of the Dahomey Gap, respectively [13]. In regions where Clade II MPXV is considered endemic, there were a total of 302 reported mpox cases from 1970-2021 [14]. Most data on Clade II mpox morbidity and mortality in West Africa have been based on observations from reports following mpox re-emergence in Nigeria, which has included 270 mpox cases since 2017 [15, 16]. Of note, cases were overrepresented among young adults rather than children, and predominantly in males, including suspected sexual contacts as well as the linkage between more severe outcomes with uncontrolled HIV

Rapid geographic expansion of Clade IIb MPXV in 2022 among non-endemic regions of the globe typified by atypical clinical presentation compared to historical data [9, 17, 18]. Clade IIb infections during the first mpox PHEIC were concentrated within dense sexual networks and primarily among males that identified as gay, bisexual, and other men who have sex with men (gbMSM) [19].

The historic burden of human mpox in Sierra Leone has been very low with only three reported infections from 1970 through to 2021 and no weekly case totals from 2022 through to the late December 2024 [4, 14, 19-21]. No mpox cases were identified in Sierra Leone between 1970 and 2014 with single cases identified in 2014 and 2017. However, a serological investigation undertaken in the Kenema District, Sierra Leone, strong IgG seropositivity among 1.3% of participants were born after the cessation of smallpox vaccination [22]. Positive IgM titers were also identified in six participants, with four being born after smallpox vaccination cessation. These data suggested that while infrequent, cryptic orthopoxvirus exposures were occurring in the absence of reported infections. However, there has been a rapid escalation in mpox cases in Sierra Leone starting in January 2025 with 3782 confirmed mpox cases reported to 07 June 2025. Concerningly, cases have been highly concentrated in the capital of Freetown (Pop. ~1.4M). Given the limited historical data for mpox burdens or clinical descriptions in West Africa, the increase burden of the disease within Sierra Leone, and the potential for further regional expansion, we sought to investigate clinical and epidemiological characteristics associated with this outbreak.

MATERIALS AND METHODS

In this retrospective observational study, we analyzed 187 mpox case reports spanning January 2025 to 31 May 2025, from multiple sample collection sites across Sierra Leone. We analysed national mpox testing and demographic data from anonymized data records provided to us directly from healthcare facilities in Sierra Leone. During the study period, swab samples from skin lesions were obtained from individuals presenting with signs and symptoms consistent with mpox at various healthcare facilities nationwide. These samples were subsequently transported to the capital, Freetown, for mpox testing at one of three laboratories: Jui Hospital Laboratory, 34 Military Hospital Laboratory, or the Central Public Health Reference Laboratory in Lakka. For

113 this investigation, Freetown case reports came from Connaught Hospital and Jui Hospital, which
114 served as the main testing site from January to March 2025. Additional mpox patients case
115 reports from other districts were also provided by Jui Hospital. Mpox testing began in Kono in
116 the third week of May 2025.

117 **Institutional Review and Ethical Clearance**

118 The Sierra Leone Ethics and Scientific Review Committee (SLERC No. 010/05/2025) and the
119 Health Research Ethics Board at the University of Manitoba, Canada (Opinion No. HS25837)
120 approved this study. We were waived from obtaining informed consent from mpox patients on
121 confidentiality purpose because we were analyzing facility-based aggregated medical records, as
122 well as anonymized patient data.

123 **RESULTS**

124 **Demographics of probable and confirmed mpox patients from January to May 2025 in**
125 **Sierra Leone**

126 From 01 January 2025 to 30 May 2025, there have been 3782 confirmed mpox cases in Sierra
127 Leone, including 20 fatalities (CFR 0.53%). Of these, 3016 cases (79.8%) have been reported
128 from the Freetown area, including both the Western Rural (757 cases) and Western Urban (2259
129 cases) regions. Of the 3782 confirmed mpox cases, we were able to access demographic
130 information for 187 cases, which spanned the period of January 2025 to May 2025 (Figure 1).
131 The majority of the available mpox patient data in this study was reported from Bo (86/187;
132 46.0%), followed by Freetown (48/187; 25.7%), including Western Urban Area (43 cases) and
133 Western Rural Area (5 cases), and Kono (37/187; 19.8%). Additional regions included
134 Moyamba, Port Loko, Tonkolili, Bombali, and Karene, each having <5 mpox patient case
135 reports. One case report was from an unknown location.

136 The earliest accessible mpox case report preceding the ongoing outbreak in Sierra Leone
137 involved a male patient aged between 26 and 35 years, who also disclosed as a person living with
138 HIV. He had no history of international travel. In December 2024, he traveled to Lungi, where he
139 reported unprotected sexual intercourse with a sex worker. Symptoms began the following day,
140 including headache, fever, progressive weakness, followed by the development of a rash and

141 lymphadenopathy. The patient also reported consuming cooked wild game, including goat,
142 sheep, and nonhuman primates. Initially suspected to have malaria, he received treatment from a
143 local Community Health Worker in Lungi. However, with no improvement in symptoms, he
144 subsequently sought traditional remedies. The patient stated that none of his close contacts had
145 been diagnosed with mpox.

146 Age and sex demographics for all probable and confirmed mpox patients included in this
147 investigation are presented in Table 1 and Figure 2. Among the cases, 101/187 identified as male
148 (54.0%) and 86/187 identified as female (46.0%). The median age among the patients with mpox
149 in this investigation was 26 years (IQR 22-34) with a higher median age among males (30 years;
150 IQR 25-39) then females (24 years; IQR 21-27). The highest proportions of patients were aged
151 16-25 years followed by those aged 26-35 years, and 36-49 years, respectively, and collectively
152 comprised 160/187 (85.6%) of all patients included in this study. Cases among males ranged
153 from two weeks-to-55 years and from 11 months-to-75 years for females. The highest proportion
154 of cases within the data sets were females aged 16-25 years (27.3%) followed by males aged 26-
155 35 years (16.6%). More than half of female patients with mpox in this study were 16-25 years
156 (51/86; 59.3%). In contrast, the highest proportion of male mpox patients were aged 26-35 years
157 and comprised 31/101 (30.7%) of male patients. Two female mpox patients self-identified as
158 commercial sex workers when asked about occupation and two male mpox patients had
159 epidemiological links to commercial sex workers with diagnosed mpox.

160 **Reported clinical and demographic characteristics for confirmed and probable mpox**
161 **patients in Sierra Leone**

162 Clinical symptom characteristics that were provided for all probable and PCR-confirmed patients
163 with mpox in this investigation are presented in Table 2. Rash, fever, headache, cutaneous
164 lesions, and generalized pain were reported among all patients, where symptom data was
165 available for analysis. Lymphadenopathy, muscle pain, sore throat, and cough were reported by
166 the majority of patients with decreasing frequency, respectively. However, all were reported by a
167 higher proportion of male patients as compared to female patients. When considering sex-
168 specific reporting, lymphadenopathy was reported by 88.9% of males as compared to 80.6% of
169 females and muscle pain was reported by 75.7% and 66.7% of male and female patients,
170 respectively. Sore throat and cough were reported by 65.9% and 58.3% of male patients,

171 respectively. In contrast, female patients reported these less frequently at 36.5% and 33.6%,
172 respectively. The median times between symptom onset and reporting to a health facility were
173 available for 94 patients with a median of 3 days (IQR 2-6). For male mpox patients (N=56), the
174 median time was 4 days (IQR 2-7) whereas for female mpox patients (N=38), the median was 3
175 days (IQR 2-4).

176 **Demographics and clinical symptom data for hospitalized mpox patients in Sierra Leone**

177 Among all confirmed and probable cases included in this investigation, 54 of 187 patients with
178 mpox (28.9%) were hospitalized. Specifically, 22 of 101 male patients (21.8%) and 32 of 86
179 female patients (37.2%) were hospitalized based on the available data. Clinical symptoms and
180 age distribution for hospitalized patients are detailed in Table 3. The median age of hospitalized
181 patients was higher for males (29 years; IQR 22-39) than females (24; IQR 22-28).

182 The highest proportion of hospitalized patients with mpox were aged 16 - 25 years (26/54;
183 48.2%), followed by those aged 26 - 35 years (11/54; 20.4%) and 36 - 49 years (9/54; 16.7%).
184 Three hospitalized patients were children under 15 years of age, with two of those under the age
185 of five. Among patients aged 16 - 25 years, the majority were female (19/26); 7/26 males in this
186 age demographic were hospitalized.

187 Clinical symptom data from hospitalized patients indicated that rash, fever, and generalized pain
188 were present in all. Lymphadenopathy was reported in 35 of 54 patients (76.1%), while sore
189 throat (21/54; 48.9%) and cough (19/54; 35.2%) were reported less frequently. Female patients
190 with mpox had higher rates of lymphadenopathy, sore throat, and cough compared to male
191 patients.

192 **DISCUSSION**

193 This investigation provides a detailed clinical and epidemiologic characterization of the 2025
194 mpox outbreak in Sierra Leone, representing the first comprehensive report of its kind during the
195 current epidemic. Between January and 31 May 2025, a total of 3782 confirmed mpox cases
196 have been reported nationwide, with the majority originating from Freetown and its surrounding
197 regions. Recent genome sequencing data has identified the hMPXV-1 (A) lineage of Clade IIb,

198 which emerged in Nigeria in 2014, among 76 of 77 genomes sequenced in the analysis [23].
199 MPXV Despite the national scale of the outbreak, detailed demographic and clinical data were
200 only accessible for 187 patients, offering a focused yet valuable lens into transmission patterns,
201 symptomology, and healthcare-seeking behaviors during the early stages of this epidemic. The
202 demographic distribution revealed that young adults, particularly those aged 16 - 35 years,
203 represented the highest burden of disease, accounting for over 66.8% of cases analyzed. This
204 suggests the expansion of mpox cases within Sierra Leone in 2025 is being driven by sustained
205 human to human transmission. A significant proportion of affected individuals were female
206 patients aged 16 - 25 years, suggesting that this demographic is playing a central role in the local
207 transmission dynamics, potentially driven by behavioral, occupational, or sociocultural factors.

208 Clinically, the presentation of mpox in this cohort was largely consistent with prior outbreak
209 reports from other regions, with universal reports of rash, fever, and generalized pain among
210 cases where symptom data was available. When considering available data assessing the time
211 between symptom onset and reporting to a healthcare facility, there was an overall median of 3
212 days (IQR 2-6). These were similar between male and female mpox patients though female
213 patients (3 days; IQR 2-4) tended to report to a healthcare facility or practitioner faster than male
214 mpox patients (4 days; IQR 2-7).

215 Hospitalization data is also consistent with outbreaks from other regions; and in the context of
216 under sampling and bias toward detecting the more severe cases coming to medical attention,
217 28.9% of mpox patients within our cohort were admitted, with a predominance of young adult
218 females aged 16 - 25 years. All hospitalized patients experienced rash, fever, and generalized
219 pain. While our data access did not include contact tracing data for individual patients, nor
220 information on epidemiological linkages between mpox patients, the concentration of mpox
221 cases within the densely populated capital of Freetown (pop. ~1.4M), is reminiscent of our recent
222 observations of mpox expansion in Kinshasa, DRC, driven by human-to-human transmission
223 [24, 25]. In both investigations, mpox patients included in our analyses included those who self-
224 identified as commercial sex workers, providing further support for dense sexual networks as a
225 focal point for mpox circulation and transmission. This is further corroborated by
226 epidemiological linkage of mpox patients with commercial sex workers who had diagnosed
227 mpox disease. In addition, many hospitalized patients in this study had densely concentrated

genital lesions providing further support for linkage of mpox transmission in Sierra Leone to sexual and intimate contacts. Recent increases in mpox cases outside of Freetown, including Bombali, Port Loko, Kono, Kenema, and Bo suggest that the mpox epidemic is expanding regionally. Whether these have been due to single or multiple introductions of mpox virus or whether these case increases are linked to sustained human-to-human transmission have yet to be determined. However, the demographic data in this report provide strong support for sustained human-to-human transmission within dense population networks. It is appreciated that the 187 case reports analyzed in this investigation only represent a small cross-section of the total patients that reported to healthcare facilities for testing and evaluation during this outbreak. Acquisition of additional case report data is ongoing; however, this remains an ongoing challenge given the rapid expansion of the outbreak across numerous locations in Sierra Leone.

This report highlights early clinical and epidemiological observations from the rapidly expanding mpox epidemic currently ongoing in Sierra Leone. Mpox cases totals in 2025 have vastly surpassed the cumulative total of all mpox cases in-country from 1970 through 2024 with the 3782 cumulative cases surpassing those of Nigeria following the re-emergence of mpox in 2017 through 2024 (3,771 suspected mpox cases) [26]. Containment and mitigation efforts, including vaccine deployment to frontline healthcare workers and those at increased risk for infection, as well as increased community engagement to at-risk populations and increased access to testing (and diagnostic infrastructure) are needed.

360 stratification. For clinical symptom data, percentages (in parentheses) represent sex-specific
361 proportions of reported clinical symptoms, where data was available.

	Males	**Females**	**Total**
N	22	32	54
Age			
Median (IQR)	29 (22-39)	24 (22-28)	25 (22-31)
0-5	2 (3.7)	1 (1.9)	3 (5.6)
6-15	0	1 (1.9)	1 (1.9)
16-25	7 (13.0)	19 (35.2)	26 (48.2)
26-35	5 (9.3)	6 (11.1)	11 (20.4)
36-49	5 (9.3)	4 (7.4)	9 (16.7)
50+	1 (1.9)	1 (1.9)	2 (3.7)
Unknown	2 (3.7)	0	2 (3.7)
Clinical Symptoms			
Rash	21 (100)	32 (100)	53 (100)
Fever	22 (100)	32 (100)	54 (100)
Lymphadenopathy	13 (65.0)	22 (84.6)	35 (76.1)
Sore Throat	8 (36.4)	13 (40.6)	21 (48.9)
Cough	7 (31.8)	12 (37.5)	19 (35.2)
Generalized pain	19 (100)	25 (100)	44 (100)
