Short title: Trends in tap water consumption disparities

The authors declare they have no conflicts of interest.

Funding statement: This work was supported by the Ann Atherton Hertzler Early Career Professorship funds, and Penn State's Population Research Institute (NICHD P2CHD041025). The funders had no role in the research or interpretation of results.

3 **Abstract:**
4 **Objective**. As tap water distrust has grown in the US with greater distrust among Black and
5 Hispanic households, we aimed to examine the most recent trends in not drinking tap water
6 including the period covering the US Flint Water Crisis and racial/ethnic disparities in these
7 trends.
8 **Design, Setting, and Participants**. We analyzed data from the cross-sectional National Health
9 and Nutrition Examination Survey data (2011–2018) for 9,439 children aged 2-19 and 17,268
10 adults. Log-binomial regressions and marginal predicted probabilities examined US nationally-
11 representative trends in tap water consumption overall and by race/ethnicity.
12 **Results**. Among US children and adults, respectively, in 2017–2018 there was a 63% (adjusted
13 prevalence ratio [PR]:1.63, 95% CI: 1.25-2.12, p<0.001) and 40% (PR:1.40, 95% CI: 1.16-1.69,

p=0.001) higher prevalence of not drinking tap water compared to 2013–2014 (pre-Flint Water Crisis). For Black children and adults, the probability of not drinking tap water increased significantly from 18.1% (95% CI: 13.4-22.8) and 24.6% (95% CI: 20.7-28.4) in 2013–14 to 29.3% (95% CI: 23.5-35.1) and 34.5% (95% CI: 29.4-39.6) in 2017–2018. Among Hispanic children and adults, not drinking tap water increased significantly from 24.5% (95% CI: 19.4-29.6) and 27.1% (95% CI: 23.0-31.2) in 2013–14 to 39.7% (95% CI: 32.7-46.8) and 38.1% (95% CI: 33.0-43.1) in 2017–2018. No increases were observed among white children and adults. **Conclusions**. Approximately 20% of US children and adults did not drink tap water post-Flint Water Crisis in 2017-2018. Black and Hispanics' probability of not drinking tap water continued to increase compared to whites.

Keywords: Tap water; health disparities; water insecurity; bottled water

Introduction

Approximately two million Americans lack basic access to drinking water[1]. However, this figure does not capture individuals who have access but do not drink their tap water. Not drinking tap water occurs for many reasons, including aesthetic considerations or distrust due to water quality violations in homes[2] or schools[3]. The Flint, Michigan Water Crisis[4], in which the Flint community was exposed to high concentrations of lead in their water from 2015 through 2016 raised national awareness[5] of tap water safety concerns in US communities[2,6]. Then, Newark, New Jersey reported a lead crisis in 2016[7] further stoking fears. Both Flint and Newark are comprised predominantly of non-white residents.

Other households in the US lack consistent access to tap water at home because of water shutoffs due to affordability issues[8], which disproportionately affect residents in low-income housing, and Black and Hispanic households[9,10]. The differential treatment of individuals in these categories increases exposure to environmental injustice and racism[11] which may affect both access to and use of tap water. Consequently, these groups are also more likely to drink bottled water[12] and sugar-sweetened beverages[13,14] that are more costly[15] and lack the protective benefits of fluoride[16] in tap water.

While previous work documented an increase in US children not drinking tap water in 2015-2016[12] during the Flint Water Crisis compared to prior years, it is critical to surveil this important health behavior as a way to monitor trust and usage of tap water. Therefore, we examined whether not drinking tap water in the US continued to increase in 2017-2018 by analyzing nationally-representative trends among children/adolescents and adults, and whether disparities in this behavior persisted by race/ethnicity.

Methods

Data come from the National Health and Nutrition Examination Survey (NHANES)[17], a cross-sectional survey of the civilian, non-institutionalized population, which uses a complex, multistage probability design. Detailed sampling procedures and methodology are described elsewhere[18]. NHANES is conducted by the National Center for Health Statistics (NCHS) and approved by their research ethics board. Children aged 7-17 years provided assent and parents provided consent for children under 18; adults consented for themselves.

This analysis uses the four most recent two-year cycles (2011–2018) because oversampling of non-Hispanic (NH) Asians began in 2011-12 allowing for an examination of this population's trends in tap water consumption, and because prior work already examined trends in Black, Hispanic and White tap water consumption from 2007-2016[12]. Response rates ranged from 77.0% in 2011–12 to 54.6% in 2017–18 for the examination component for youth aged 1-19 years, and from 64.5% in 2011–12 to 45.3% in 2017–18 for adults aged 20+.

To assess the prevalence of not drinking tap water, we analyzed responses to the dietary recall question: "When you drink tap water, what is the main source of the tap water?" If respondents reported not drinking tap water, they were coded as "did not drink tap." All others were coded as "drank tap water"[16,19]. A proxy responded to interview questions for children aged ≤5 years; interviews for children aged 6–11 years were conducted with proxy assistance while children aged ≥12 years responded themselves. If they responded that they did not know their primary source, they were excluded from analyses.

For robustness analyses, we analyzed day-one 24-hour dietary recall data and dichotomized tap water consumption and bottled water consumption as >0 ml or 0 ml following prior work[13]. This allowed for a comparison of consumption on a given day to self-reports of not drinking water from their main source of tap and if not drinking tap water shifted consumption to bottled water.

Statistical analyses

A 2-sided *P*-value of .05 was used to assess statistical significance. Multiple log-binomial regression models were estimated since prevalence of not drinking tap was >10%[12]. As there were no significant race/ethnicity by survey cycle interactions (all p>0.05), we estimated the regressions and covariate-adjusted time-trends without interaction terms. We used the 2013-14 survey cycle as the reference category as it was the last cycle prior to the Flint Water Crisis. We plotted trends from the log-binomial regressions using marginal standardization[20] to generate predicted probabilities by self-reported race/ethnicity (white, Black, Asian, Hispanic, or other). We adjusted for the range[21] of the following covariates: age (2-5, 6-11, 12-19, 20-39, 40-59, 60+), sex, federal income to poverty ratio (FIPR; ratio of family income to the federal poverty guideline[22]: ≤130%, 131-350%, >350%), household reference educational attainment (for children/adolescents; high school graduate/GED equivalent and some college were released

87 combined) and educational attainment (for adults), and whether respondents were born in the US
88 or not[12,19].
89 As robustness analyses, we re-estimated log-binomial regressions models as described
90 above with the dichotomized outcome of not drinking any tap water (0 ml) on a given day using
91 the 24-hour dietary recall. We repeated this analysis with the dichotomized outcome of any (>0
92 ml) bottled water intake.
93 All analyses accounted for the complex survey design, including day-one dietary sample
94 weights, which adjusted for oversampling, non-response, non-coverage, and day of week[18,23] and
95 incorporated guidelines from NCHS[24]. Statistical analyses were conducted using Stata V15.1
96 (Statacorp, College Station, TX).
97
98 **Results**
99 Data for the primary analyses were analyzed for 9,439 children and 17,268 adults with
100 complete covariate information (**Table 1**). Among children/adolescents and adults, respectively,
101 in the post-Flint period (2017–2018) there was a 63% (adjusted prevalence ratio [PR]:1.63,
102 95%CI:1.25-2.12, p<0.001) and 40% (PR:1.40, 95%CI:1.16-1.69, p=0.001) higher prevalence of
103 not drinking tap water compared to pre-Flint (2013–2014), respectively (**Figure 1a-b;**
104 **Supplemental Table 1**: Models 1-2). Overall, the probability of not drinking tap increased
105 significantly from 12.3% (95%CI:9.5-15.0) and 13.9% (95%CI:11.8-16.0) among children and
106 adults, respectively in 2013–2014 to 19.9% (95%CI:16.0-23.8) and 19.5% (95%CI:16.5-22.5) in
107 2017–2018.
108 Hispanic, Black, and Asian children/adolescents and adults had significantly higher
109 prevalence of not drinking tap than white persons (all p<0.001, **Figure 1a-1b; Supplemental**
110 **Table 1:** Models 1-2). Lower income, less educational attainment, and being born outside the US
111 were associated with higher prevalence of not drinking tap water (**Figure 1a-1b**).
112 Covariate-adjusted trends by race/ethnicity of not drinking tap water are presented in
113 **Figure 2a-2b**. Among Black children/adolescents and adults, the probability of not drinking tap
114 water increased significantly from 18.1% (95CI:13.4-22.8) and 24.6% (95%CI:20.7-28.4) in
115 2013–14 to 29.3% (95%CI:23.5-35.1) and 34.5% (95%CI:29.4-39.6) in 2017–18, respectively.
116 Among Hispanic children/adolescents and adults, not drinking tap increased from 24.5%

117 (95%CI:19.4-29.6) and 27.1% (95%CI:23.0-31.2) in 13-14 to 39.7% (95%CI:32.7-46.8) and
118 38.1% (95%CI:33.0-43.1) in 2017–2018, respectively (**Figure 2a-2b**).
119
120 *Robustness analysis*
121 In robustness analyses, we used data from 10,254 children/adolescents and 17,829 adults
122 with valid dietary recall data, slightly more than the primary analyses due to fewer missing
123 responses. Results of the log-binomial regressions examining not drinking tap water on a given
124 day were slightly attenuated but largely consistent with main analyses (**Supplemental Table 2**).
125 Overall for children/adolescents and adults, the prevalence of not drinking tap water was 14.0%
126 (PR=1.14; 95%CI:0.98-1.33) and 12.6% (PR=1.13; 95%CI:1.01-1.25) higher in 2017-2018 than
127 2013-2014. As in primary analyses, Black and Hispanic children/adolescents and adults had
128 significantly higher prevalence of not drinking any tap water on a given day than white persons
129 (**Supplemental Table 2**, Models 1-2).
130 In the second analysis, prevalence of any bottled water consumption on a given day was
131 significantly higher overall for both children (PR: 1.26; 95%CI:1.12-1.41) and adults (PR: 1.25;
132 95%CI:1.12-1.40) in 2017-18 than in 2013-14. Further, Black, Asian, and Hispanic persons all
133 had higher prevalence of drinking bottled water than white children and adults, respectively
134 (**Supplemental Table 3**, Models 1-2).
135
136 **Discussion**
137 This study used nationally-representative data to examine trends and racial/ethnic
138 disparities in tap water consumption among US children and adults which included the pre- and
139 post-Flint period as national awareness about water safety concerns increased. There was little
140 change between 2011-14, but probability of not drinking tap water increased successively from
141 2013-14 to 2017–2018, with Hispanic, Black, and Asian individuals being more likely to not
142 drink tap water than whites. Self-reported race/ethnicity continued to be the largest predictor of
143 not drinking tap water of all covariates examined as the differential treatment of individuals in
144 these categories increases exposure to environmental injustice and racism[11].
145 While recent studies indicate that up to two million Americans lack basic water access[1] -
146 particularly in urban areas[25] - our study indicates the broader problem is far more pervasive. In
147 2017–2018, ~20% of US children/adolescents and adults did not drink tap water, which

148 translates into 14.8 million children and 46.6 million adults using the NCHS Census population
149 totals. Tap water consumption has health benefits through fluoride delivery that lowers risk of
150 dental caries[16]. Moreover, when individuals do not drink water they consume double the calories
151 from sugar-sweetened beverages[13].

152 We found persistent racial/ethnic disparities, and that among Hispanic and Black
153 households their probability of not drinking tap has increased recently. Prior research found that
154 Black and Hispanic populations are less likely to drink tap water[12,19] due to higher inequities in
155 water access[9] and distrust among these populations[26]. A recent paper examining trends in tap
156 water intake using NHANES 2011-2016 data did not find significant changes in the volume of
157 tap water consumed over time but did uncover increases in the volume of bottled water
158 consumed[27]. While our primary variable was based on whether persons consumed their tap water
159 rather than the average volume of water consumed, our results were robust when using a
160 dichotomous variable of any tap water intake from the 24-hour dietary recall. It is critical to
161 monitor trends in the lack of any tap water consumption beyond average mean intakes because
162 this can provide a window into potential underlying water insecurity. Second, we also found that
163 prevalence of any bottled water consumption on a given day was 25% higher in 2017-18 than
164 2013-14, supporting the recent trends of increasing bottled water intake in the US[12,27].

165 Environmental injustice and racism contribute to these disparities[9] as water quality
166 violations[28] and water shutoffs[9] disproportionately affect these communities. Drinking water
167 quality violations often occur at the intersection of race and class where low-income Black and
168 Hispanic communities are at the greatest risk of marginalization[29]. Our results suggest little
169 progress in addressing these inequities. Increased national awareness of water quality violations
170 following the Flint Water Crisis, emerging local water contaminant exceedances in other cities
171 like Newark, NJ, or other unknown factors may help explain our findings. In particular,
172 increasing reports of lead violations in school drinking water, following increasing requirements
173 to test at the tap, have likely heightened concerns regarding tap water safety[3]. Future studies
174 should be conducted to confirm these hypotheses.

175 Study limitations include the inability to know why participants did not drink their tap
176 water as follow-up questions were not asked. However, we used two measures of tap water
177 consumption to provide additional internal validity of results and find that shifts to bottled water
178 occurred. This study is limited by not having geographical data, but its goal was to examine

recent national trends in tap water consumption rather than geographic differences. Recent work has demonstrated that structural issues like precarious housing within communities of color increases risk of incomplete plumbing[25,30]. Tap water filtration was discontinued following the 2009-2010 survey and thus was not controlled for. However, prior work has demonstrated that use of tap water filters do not have an overall effect on these national estimates of tap water consumption[12]. NCHS addressed the declining response rates through the sampling weights, which further took into account non-response and loss of screener to examination[18].

Conclusion

Approximately 63% and 40% more Black and Hispanic children and adults did not drink their tap water in 2017–18 compared to 2013-14. That approximately 61.4 million Americans did not drink tap water represents a substantial opportunity to improve public health nutrition. Further, that bottled water consumption continues to increase while Black, Asian, and Hispanic households are more likely to rely on it levies additional socioeconomic strain. Policies that address the root environmental injustices that low-income and minority communities' face in accessing safe tap water are necessary to halting the growing racial disparity gap observed in tap water consumption[26]. To design meaningful solutions more work with communities of color is needed to understand the various factors that contribute to eschewing tap water.

298 **Notes:** n=9,439 children aged 2-19; n=17,268 adults; models adjusted for nativity status, sex, age
299 group, income level (federal income to poverty ratio), and educational attainment (of household
300 reference for children, self for adults); dashed line at 2013–2014 indicates beginning of Flint,
301 Michigan Water Crisis. Built from models shown in Supplemental Table 1.
