Abstract

Background.

The elderly are highly vulnerable to severe Covid-19. Waning immunity and emergence of Omicron have caused concerns about reduced effectiveness of Covid-19 vaccines. The objective was to estimate vaccine effectiveness (VE) against severe Covid-19 among the elderly.

Methods.

This nationwide, register-based cohort analysis included all residents aged 70 years and over in Finland. The follow-up started on December 27, 2020, and ended on March 31, 2022. The outcomes of interest were Covid-19-related hospitalization and intensive care unit (ICU) admission timely associated with SARS-CoV-2 infection. VE was estimated as one minus the hazard ratio comparing the vaccinated and unvaccinated and taking into account time since vaccination. Omicron-specific VE was evaluated as the effectiveness observed since January 1, 2022.

Results.

The cohort included 896220 individuals. Comirnaty (BioNTech/Pfizer) VE against Covid-19-related hospitalization was 93% (95% CI 89%–95%) and 85% (95% CI 82%–87%) 14–90 and 91–180 days after the second dose; VE increased to 95% (95% CI 94%–96%) 14–60 days after the third dose. VE of other homologous and heterologous three dose series was similar. Protection against severe Covid-19 requiring ICU treatment was even better. Since January 1, 2022, Comirnaty VE was 98% (95% CI 92%–99%) and 92% (95% CI 87%–95%) 14–90 and 91–180 days after the second and 98% (95% CI 95%–99%) 14–60 days after the third dose.

Conclusions.

VE against severe Covid-19 is high among the elderly. It waned slightly after two doses, but a third restored the protection. VE against severe Covid-19 remained high even after the emergence of Omicron.

Keywords: Covid-19 hospitalization, Covid-19 vaccines, elderly cohort, SARS-CoV-2 omicron variant, waning vaccine effectiveness

Background

The elderly are highly vulnerable to severe coronavirus disease 2019 (Covid-19) (1) and, therefore, protecting them is essential to reduce the disease burden caused by the severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2). Covid-19 vaccinations prevent SARS-CoV-2 infections and decrease the number of Covid-19 hospitalizations in a population (2–7).

As many other European countries, Finland has mainly used two mRNA Covid-19 vaccines, Comirnaty and Spikevax, and one adenovirus vector Covid-19 vaccine, Vaxzevria (Table 1). In September 2021, Finland started its booster vaccination campaign to improve the protection especially for the elderly (8). The initial recommendation was to adhere to homologous vaccine series, but lately with increasing evidence of good effectiveness (9,10), heterologous series have also been encouraged.

Vaccine effectiveness (VE) generally describes the protective direct effect of vaccination. In the elderly, VE against severe Covid-19 is high after the second dose, but it decreases during the following six months (4,11–14). A third dose increased the VE against infection among adults in multiple observational studies (11,15–18). However, only a few studies have investigated how well the third dose boosts the VE against severe disease among the elderly (17,19,20). Furthermore, VE may decrease because of the recently emerged Omicron variant, which is more capable of evading both natural and vaccine-induced immunity than previous variants (15,16,21–23). Knowledge of VE against severe Covid-19 caused by Omicron is still limited (16,21,23–25) and discussion of the need for further booster doses in the elderly has commenced.

The objective of this study was to estimate the effectiveness of Covid-19 vaccines against severe Covid-19 requiring hospitalization or intensive care unit (ICU) treatment in the elderly in Finland after two and three doses. The effects of time since vaccination, different vaccine series, age and presence of comorbidities on VE were of particular interest. In addition, this study aimed to evaluate the impact of the recently emerged Omicron variant on VE.

Methods

To estimate the effectiveness of Covid-19 vaccines in the elderly population in Finland, we conducted a nationwide, register-based cohort analysis starting on December 27, 2020, and ending on March 31, 2022. The study population was defined as all individuals aged 70 years and over at the beginning of the study and registered in the Population Information System as resident in Finland since January 1, 2020. The unique personal identity code assigned to all permanent residents in Finland allowed linking individual-level data from different sources.

The primary outcome was Covid-19-related hospital admission timely associated with a laboratory-confirmed (by polymerase chain reaction or antigen detection assay) SARS-CoV-2 infection. Using the Care Register for Health Care, which records data on all patients discharged from inpatient care in Finland, we defined Covid-19-related hospitalization as any inpatient encounter with a primary diagnosis of Covid-19 (International Classification of Diseases, 10th revision: U07.1, U07.2), acute respiratory tract infection (J00–J22, J46) or severe complication of lower respiratory tract infections (J80–84, J85.1, J86). A hospitalization was considered timely associated with an infection recorded in the National Infectious Diseases Register if the positive specimen was collected up to 14 days before or seven days after the hospital admission.

The secondary outcome was Covid-19-related ICU admission. ICU admissions were identified from the Finnish Intensive Care Consortium's Quality Register for Intensive Care, which records data on all patients treated in an ICU in Finland. We considered any admission as Covid-19 related if it was marked by the treating physician as due to Covid-19 and if the patient was laboratory-confirmed SARS-CoV-2 positive during the stay.

The exposure was Covid-19 vaccination recorded in the National Vaccination Register, which covers the whole population irrespective of whether they are served by public or private primary health care providers. We distinguished between the three vaccine brands Comirnaty, Spikevax and Vaxzevria and the number of administered doses. The time since vaccination was taken into account by categorizing the time since the last dose using the following cut points: days 21 and 84 after the first dose, days 14, 91 and 181

96 after the second dose, and days 14 and 61 after the third dose. Thus, a vaccinee's exposure state changed
97 over time. Being unvaccinated was the reference state.

98 We considered age, sex, region of residence, residence in a long-term care facility, influenza vaccination in
99 2019–2020, number of nights hospitalized between 2015 and 2019 and presence of predisposing
100 comorbidities or medical therapies as confounders. The first three confounders were taken from the
101 Population Information System. Information on whether a subject was in long-term care at the beginning of
102 the study or vaccinated against influenza in the last pre-pandemic season were collected from the Care
103 Register for Social Care and the National Vaccination Register, respectively. We used the data in the Care
104 Register for Health Care from 2015 onwards to count the number of nights hospitalized between 2015 and
105 2019 and to assess the presence of comorbidities or medical therapies that predispose to severe Covid-19
106 according to a recent study of predictors of Covid-19 hospitalization (26). We completed the collection of
107 data on predisposing comorbidities and medical therapies with primary health care records and
108 prescription data as outlined in Supplementary Tables 1-2.

109 Each study subject was considered at risk of the primary and secondary outcomes from the beginning of
110 the study until the first occurrence of any of the following events: outcome of interest, death, day 14 after
111 any laboratory-confirmed SARS-CoV-2 infection, vaccination with an unidentified vaccine, a heterologous
112 second vaccination, vaccination with the third dose prior to the start of the booster campaign
113 (approximated by September 17, 2021), a fourth vaccination, or end of study. All those events other than
114 the outcome of interest led to censoring before or at the end of the study.

115 Using Cox regression with time in the study as the underlying time scale, we compared the hazard of the
116 two outcomes in vaccinated study subjects with the corresponding hazard in the unvaccinated. The effect
117 measure of interest was VE, quantified as one minus the hazard ratio adjusted for the seven confounders
118 categorized as outlined in Table 2. For each VE estimate, we computed either the 95% Wald confidence
119 interval (CI) or, if there were no cases in one of the two groups, the p-value of the likelihood-ratio test. We
120 stratified the analysis by age group and presence of comorbidities or medical therapies. Because of the

emergence of Omicron (Supplementary Figure 1), we also estimated VE by calendar time, conducting a separate regression analysis for each quarter.

To rule out residual confounding, we quantified the association between Covid-19 vaccination and a potential negative control outcome: inpatient encounters due to injury, poisoning and certain other consequences of external causes (International Classification of Diseases, 10th revision: S00–T98) recorded in the Care Register for Health Care. Each study subject was considered at risk of this outcome from the beginning of the study until the first occurrence of any of the following events: injury, death, vaccination with an unidentified vaccine or a heterologous two-dose series, vaccination with the third dose prior to September 17, 2021, or with a fourth dose, or end of study. We compared the hazard of the control outcome in vaccinated study subjects with the corresponding hazard in the unvaccinated using Cox regression and expected to find no difference between the groups.

The significance level was set to 5%. The validity of the proportional hazards assumption was examined visually by plotting the cumulative hazards over time. All analyses were performed in R 4.1.2 (R Foundation for Statistical Computing, Vienna, Austria). Results concerning the first dose, less common (less than 2000 person-years) vaccine series and the first two weeks after vaccination are presented in the supplementary data only.

Results

The study cohort included 896 220 individuals aged 70 years and over, and thus 99.8% of the elderly population in Finland (Supplementary Tables 3-4). At the end of the study, only 5% of those still considered at risk of Covid-19 hospitalization were unvaccinated; the majority (6% and 65%) were double- or triple-vaccinated with Comirnaty (Supplementary Table 5, Supplementary Figure 2). The median length of the dosing interval between the first and second dose and the second and third dose was 84 (interquartile range, 84–84) and 188 (interquartile range, 181–199) days, respectively. At the end of the study, the triple vaccinated who were still considered at risk of Covid-19 hospitalization had received their third dose, on

146 average, 106 (interquartile range, 93–120) days ago. Table 2 shows the distribution of person-years by
147 vaccination status. The younger and community-dwelling elderly contributed proportionally less vaccinated
148 person-time than older individuals or those in long-term care. The younger and community-dwelling elderly
149 had, however, received their first dose later than older individuals and those in long-term care
150 (Supplementary Table 5).

151 We observed 2234 Covid-19 hospitalizations and 296 ICU admissions, of which 793 and 159 were among
152 the unvaccinated (Table 3, Supplementary Figure 3, Supplementary Tables 6-7). In the first 14–90 days since
153 the second dose of Comirnaty, the VE against hospitalization was 93% (95% CI 89%–95%). In the following
154 90 days, VE decreased to 85% (95% CI 82%–87%) and subsequently rose to 95% (95% CI 94%–96%) in the
155 first 14–60 days since the third dose (Figure 1, Supplementary Table 8). The point estimates of VE against
156 ICU admission were even higher (Figure 1, Supplementary Table 9). The only vaccine series with a
157 statistically significantly lower VE than the corresponding homologous Comirnaty series was the two-dose
158 homologous Vaxzevria series whose effectiveness against hospitalization was 74% (95% CI 60%–83%) in the
159 first 91–180 days.

160 Increasing age and comorbidities decreased the VE against hospitalization, yet the observed trend of
161 waning remained unchanged (Supplementary Tables 10-11). In the 14–90 and 91–180 days after the second
162 dose, the effectiveness of Comirnaty was 95% and 87% in 70-79-year-olds and 87% and 81% in 80-89-year-
163 olds. In the 91–180 days after the second dose, the presence of either moderately or highly predisposing
164 comorbidities reduced the VE from 92% to 83% or 82%. In the 14–60 days after the third dose of
165 Comirnaty, the presence of comorbidities lowered the VE from 98% to 95% or 93%.

166 The effectiveness of Comirnaty was nearly constant over calendar time (Figure 2, Supplementary Figure 4).
167 In the fourth quarter of 2021 (Q4), the VE against hospitalization was 90% (95% CI 78%–96%) in the first
168 14–90 days since the second vaccination and 96% (95% CI 93%–97%) in the first 14–60 days since the third
169 vaccination (Figure 2, Supplementary Table 12). The corresponding estimates for the first quarter of 2022
170 (Q1), which was dominated by Omicron, were 91% (95% CI 83%–95%) and 94% (95% CI 92%–95%),

171 respectively (Figure 2, Supplementary Table 13). However, while in Q4 there was almost no difference in
172 point estimates in the 14–90 and 91–180 days after the second dose, in Q1 VE seemed to drop to 75% (95%
173 CI 62%–83%) in the 91-180 days after the second dose (Figure 2). In both quarters, the median times since
174 the second dose among those vaccinated 14–90 days ago (Q4: 63 days; Q1: 59 days) and 91–180 days ago
175 (Q4: 146 days; Q1: 130 days) were similar.

176 The control outcome, i.e., injuries, occurred 36 747 times in the study cohort. Without differentiating
177 between vaccines, number of doses and time since vaccination, we estimated the hazard ratio at 0.96 (95%
178 CI 0.93–1.00) and, thus, detected no statistically significant difference between the vaccinated and the
179 unvaccinated. However, the hazard of injury in those vaccinated with Spikevax was higher than in the
180 unvaccinated (Supplementary Table 14). The cumulative hazards in vaccinated and unvaccinated individuals
181 were proportional over time (Supplementary Figure 5).

182

183 Discussion

184 In this study of a nationwide elderly cohort, the Covid-19 vaccines used in Finland were highly effective
185 against severe Covid-19. After the second and third dose, the VE against Covid-19-related hospitalization
186 and ICU admission was over 90% for both Comirnaty and Spikevax. However, already during the first 6
187 months after the second dose, we observed signs of waning VE. Although the confidence intervals
188 overlapped, VE against hospitalization appeared to decrease faster than VE against ICU admission. A third
189 dose restored the level of protection to over 90%. Interestingly, the VE was nearly constant during the
190 study period despite the sporadic emergence of new variants. However, the gradual drop in point estimates
191 of VE against hospitalization was more evident in the first quarter of 2022, which might be an indicator of
192 intensified waning after the second dose due to Omicron.

193 We found no meaningful difference in the effectiveness of the two mRNA vaccines. The effectiveness of
194 Vaxzevria was, however, slightly lower, although it was still better than the average protection observed
195 among the elderly after seasonal influenza vaccination (27,28). Nevertheless, individuals who were first

196 vaccinated with two doses of Vaxzevria and later boosted with mRNA vaccine were as well protected as
197 those who received three doses of mRNA vaccine.

198 The present study is concordant with other studies that were conducted prior to the emergence of
199 Omicron and found limited waning of VE against Covid-19-related hospitalization during the first six months
200 after the second dose in the elderly (4,7,13,14,29). In England, the VE against hospitalization decreased
201 from initially excellent 98% to 91% within 5 months from the second vaccination with Comirnaty (4). As in
202 the present study, Vaxzevria did not offer as high protection as Comirnaty and the VE was generally lower
203 among individuals with chronic illnesses (4). In line with our findings, VE has also been reported to be
204 reduced in the elderly aged 80 years and over compared to the younger elderly (14). Due to enhanced
205 immunosenescence and illness- or treatment-induced immunosuppression, the protection offered by
206 Covid-19 vaccines may, thus, be weaker among the very fragile elderly, such as residents of long-term
207 facilities.

208 Recent studies of adult populations have estimated the VE against severe Covid-19 caused by Omicron at
209 50–90% after the second dose (16,21,24,25,30) and at approximately 90% after the third dose
210 (16,21,25,30). Surprisingly, our results from the Omicron-dominated first quarter of 2022 match the upper
211 limits of these estimates, although our study was restricted to elderly adults, in which VE is expected to be
212 lower than that in younger adults (4,13,31). High VE against severe Covid-19 caused by Omicron may
213 partially explain the relatively low hospital burden during the Omicron wave in many European countries
214 despite skyrocketing infection rates (32). It is difficult to foresee how long the high level of protection will
215 last. However, this study and another analysis (30) showed that the VE against severe Covid-19 remained at
216 approximately 90% for at least 2–3 months after the third vaccination. The decision-making regarding the
217 recommendation of a fourth dose for risk groups, such as the elderly, needs further evidence on the
218 duration of natural and vaccine-induced immunity as well as VE against severe Covid-19 in various
219 epidemiological settings.

220 Finland is one of the few countries that used an extended dosing interval of 12 weeks between the first and
221 second dose due to shortage of Covid-19 vaccines in the early stage of the vaccination campaign (33). This
222 interval is considered more immunogenic and might enhance VE against severe disease compared to the
223 standard dosing interval of 3–4 weeks (7,34,35). Therefore, our results of higher VE might be explained by
224 the longer dosing interval.

225 The present study has three major strengths. First, the nationwide cohort was highly representative as it
226 covered essentially the whole elderly population in Finland. Second, the Finnish setting minimizes the risk
227 of detection bias. Hospital care in Finland is equally accessible to all permanent residents due to the
228 national health insurance resulting in low or no costs. Hospitalized patients with Covid-19 symptoms have
229 been tested at low threshold irrespective of their vaccination status and the testing capacities in hospitals
230 were at no point exhausted. Therefore, we assume that practically all elderly Covid-19 cases with severe
231 symptoms requiring hospital care were identified as part of routine clinical practice and were thus eligible
232 for inclusion in this study. Furthermore, we were able to exclude cases with concomitant asymptomatic or
233 mild SARS-CoV-2 infection primarily hospitalized for other reasons than Covid-19. Third, we performed a
234 negative control outcome analysis, which demonstrated that residual confounding after covariate
235 adjustment would be negligible. Only those vaccinated with Spikevax had a statistically significantly higher
236 risk of injuries than the unvaccinated indicating the presence of residual confounding due to differential
237 behavior or frailty.

238 Although the national registers are known to be comprehensive and have been well maintained before and
239 during the Covid-19 pandemic, the accuracy of the data has not been validated and information bias cannot
240 be ruled out. Moreover, we assumed that the study population was randomly mixing so that vaccinated
241 and unvaccinated subjects were equally exposed to the virus. Unfortunately, we have no data to support
242 this assumption and differential vaccine uptake in particularly sheltered subpopulations such as residents of
243 long-term care facilities may have thus led to bias. Although our findings may also apply to other
244 populations of similar age, they do not necessarily apply to other outcomes. VE against mild disease or

asymptomatic infection is likely lower than VE against severe disease. Another limitation is that the data do not allow estimation of variant-specific VE. As a surrogate we stratified the analysis by calendar time and used sequencing data to show which variant dominated each quarter.

Conclusions

Since their introduction at the end of 2020, Covid-19 vaccines have been highly effective in preventing severe outcomes, such as Covid-19-related hospitalization and ICU admission, in the elderly, who carry the heaviest disease burden in a population. In our study, we observed signs of waning VE during the first six months after completion of a two-dose series, but a third dose restored the high level of protection for at least 2–3 months. Our analysis of data from the first quarter of 2022 suggests that the third dose still confers high protection against severe Covid-19 even after emergence of Omicron.

Declarations

Ethics approval and consent to participate. By Finnish law, the Finnish Institute for Health and Welfare (THL) is the national expert institution to carry out surveillance on the impact of vaccinations in Finland (Communicable Diseases Act, https://www.finlex.fi/en/laki/kaannokset/2016/en20161227.pdf). Neither specific ethical approval of this study nor informed consent from the participants was needed.

Consent for publication. Not applicable.

Availability of data and materials. By Finnish law, the authors are not permitted to share individual-level register data. The computing code is available upon request.

Competing interests. No financial conflicts related to this study. Finnish Institute for Health and Welfare (THL) conducts Public-Private Partnership with vaccine manufacturers and has received research funding from Sanofi Inc., Pfizer Inc., and GlaxoSmithKline Biologicals SA for non-COVID-19-related studies. AAP has been an investigator in these studies but has received no personal remuneration.

Funding. No external funding, the study was solely conducted by the governmental public health institution of Finland.

Authors' contributions. UB, EP, TL, TK, HN and AAP participated in the conceptualization of the study. UB conducted the statistical analysis and EP reviewed the literature. UB and EP drafted the manuscript. UB, EP, TL, TK, HN and AAP gave comments and revised the manuscript.

Acknowledgments. The authors thank Heini Salo and Toni Lehtonen for the register-based identification of individuals with medical conditions predisposing to severe Covid-19 as well as Dorothée Obach, Eveline Otte im Kampe and Kari Auranen for their valuable comments during the conceptualization of the study (DO, EOiK) and manuscript revision (KA). Additional thanks go to all the colleagues at the Finnish Institute for Health and Welfare (THL) who curate the register data.

Tables

Table 1. Covid-19 vaccines under study

Trade name	International nonproprietary name	Trial name	Manufacturer	Vaccine type	Available in Finland
Comirnaty	Tozinameran	BNT162b2	BioNTech/Pfizer	mRNA vaccine	Since December 27, 2020
Spikevax	Elasomeran	mRNA-1273	Moderna	mRNA vaccine	Since January 20, 2021
Vaxzevria	ChAdOx1-S [recombinant]	AZD1222	Oxford/AstraZeneca	Adenovirus vector vaccine	From February 10 to November 30, 2021

Table 2. Distribution of person-years in the study of vaccine effectiveness against Covid-19 hospitalization.

	Not vaccinated, person-years (%)	Vaccinated, person-years (%)
Age in years		
70-79	173 830 (24)	535 938 (76)
80-89	57 939 (19)	246 105 (81)
90-115	13 068 (22)	47 634 (78)
Sex		

Male	105 628 (23)	350 917 (77)
Female	139 209 (23)	478 761 (77)
Region of residence		
Helsinki-Uusimaa	56 435 (22)	202 126 (78)
Åland	1145 (19)	4786 (81)
Northern and Eastern Finland	61 478 (23)	205 852 (77)
Southern Finland	59 279 (23)	197 393 (77)
Western Finland	66 501 (23)	219 521 (77)
In long-term care		
No	233 993 (23)	779 369 (77)
Yes	10 844 (18)	50 309 (82)
Influenza vaccination in 2019–2020		
No	133 875 (29)	335 681 (71)
Yes	110 963 (18)	493 997 (82)
Nights hospitalized between 2015 and 2019		
0	132 975 (24)	429 964 (76)
1-5	50 008 (22)	181 812 (78)
6-20	35 615 (22)	126 826 (78)
21+	26 240 (22)	91 077 (78)
Presence of comorbidities or medical therapies[a]		
No predisposing comorbidities	84 412 (24)	261 428 (76)
Only moderately predisposing comorbidities or medical therapies	65 980 (22)	232 391 (78)
At least one highly predisposing comorbidity or medical therapy	94 445 (22)	335 859 (78)
Presence of particular comorbidities or medical therapies[a]		
Severe heart disease	93 843 (22)	337 889 (78)
Type 2 diabetes mellitus	52 035 (22)	182 964 (78)
Immunosuppressive medication	35 443 (22)	127 002 (78)
Actively treated cancer	31 410 (22)	114 354 (78)
Severe chronic respiratory disease	26 198 (22)	93 213 (78)
Neurological condition affecting breathing	22 431 (22)	79 939 (78)
Autoimmune disease	17 062 (22)	60 089 (78)
Type 1 diabetes mellitus or adrenal insufficiency	13 627 (23)	46 922 (77)
Sleep apnea	11 867 (21)	43 736 (79)
Severe kidney disease	5548 (22)	19 162 (78)
Psychotic disease	3833 (29)	9282 (71)
Severe chronic liver disease	1165 (25)	3568 (75)
Organ or stem cell transplantation	560 (22)	1962 (78)
Severe disorder of the immune system	398 (23)	1369 (77)
Down syndrome	3 (19)	13 (81)

405 [a] See study of predictors of Covid-19 hospitalization (26) and Supplementary Tables 1-2.

This tabulation uses a binary vaccination status without distinguishing between vaccine brands, number of doses and time since vaccination.

Table 3. Cases, person-years and cumulative risk (per 100 000) by vaccine, dose and days since last vaccination.

	Covid-19-related hospital admission			Covid-19-related ICU admission		
	Cases	Person-years	Risk[a]	Cases	Person-years	Risk[a]
Not vaccinated	793	244 838	1313	159	244 856	238
