23 or decision to submit the manuscript for publication.

Physician Suicide: A Scoping Review to Highlight Opportunities for Prevention

24 Abstract

25 **Objective:** The aim of this scoping review is to map the current landscape of published research and
26 perspectives on physician suicide. Findings could serve as a roadmap for further investigations and
27 potentially inform efforts to prevent physician suicide.

28 **Methods:** Ovid MEDLINE, PsycInfo, and Scopus were searched for English-language publications
29 from August 21, 2017 through April 28, 2018. Inclusion criteria were a primary outcome or thesis
30 focused on suicide (including suicide completion, attempts, and thoughts or ideation) among medical
31 students, postgraduate trainees, or attending physicians. Opinion articles were included. Studies that
32 were non-English, or those that only mentioned physician burnout, mental health or substance use
33 disorders were excluded. Data extraction was performed by two authors.

34 **Results:** The search yielded 1,596 articles, of which 347 articles passed to the full-text review round.
35 The oldest article was an editorial from 1903; 210 (60.3%) articles were published from 2000 to
36 present. Authors originated from 37 countries and 143 (41.2%) were opinion articles. Most discussed
37 were suicide risk factors and culture of practice issues, while least discussed themes included public
38 health and postvention.

39 **Conclusions:** Consistency and reliability of data and information about physician suicides could be
40 improved. Data limitations partly contribute to these issues. Also, various suicide risk factors for
41 physicians have been explored, and several remain poorly understood. Based on this scoping review,
42 a public health approach, including surveillance and early warning systems, investigations of sentinel
43 cases, and postvention may be impactful next steps in preventing physician deaths by suicide.

44 1 Introduction

45 Physician suicide is a significant problem for the medical community and general public and is
46 poorly understood, suggesting that important knowledge and implementation gaps towards
47 prevention remain. To address this gap, this literature review aims to describe the state of current
48 knowledge and research on physician suicidal behaviors among medical students, postgraduate
49 trainees, including residents and fellows, and physicians. Suicide is estimated to occur at a higher rate
50 among physicians than the general population and perhaps even other professions (1,2), however,
51 estimates by profession vary (3). Several medical organizations have begun launching various
52 initiatives to address physician well-being, yet efforts to address physician suicide remain
53 organization- or institution-specific. The aim of this scoping literature review is to map the current
54 landscape of published research and perspectives on physician suicide. Findings could serve as a
55 roadmap for informing further study, evidence-based policy, and interventions to prevent physician
56 suicide.

57 2 Methods

58 This scoping review was conducted following the Arksey and O'Malley framework as expanded
59 upon and outlined within the Joanna Briggs Institute Reviewers' Manual (4,5). A scoping review
60 differs from other reviews such as a systematic review which gathers and assesses the quality of
61 quantitative evidence to report on the effectiveness of a particular intervention in achieving a certain
62 outcome (6). The research question was broadly designed to gather and analyze articles that mention
63 physician suicide. No date range for the search was specified. The initial searches were performed on
64 August 21, 2017 in Ovid MEDLINE, and October 11, 2017 in Ovid PsycINFO. Authors contributed
65 seed articles that they had previously identified as relevant to physician suicide (2,7–10), which were

Physician Suicide: A Scoping Review to Highlight Opportunities for Prevention

66 analyzed by the medical librarian co-author. Search terms and databases were then selected and
67 tested based on this analysis. The search strategy also underwent a peer review process with two
68 additional medical librarians. An updated search was run again on April 28, 2018 in Ovid
69 MEDLINE, PsycINFO, and Scopus. Detailed search terms are available in Appendix 1.

70 Inclusion criteria were English-language papers with a primary outcome, measure, or thesis focused
71 on death by suicide or suicidal behaviors among physicians, including suicide attempts, and suicidal
72 thoughts and ideation. Physicians included medical students, postgraduate trainees (residents and
73 fellows), and physicians at any career stage. Opinion articles were also included, if they otherwise
74 met inclusion criteria; these included perspectives, letters to the editor or their replies, essays, and
75 viewpoints with a focus specifically on physician suicide. Exclusion criteria were non-English
76 publications and those only pertaining to physician burnout, mental health, substance use disorders,
77 or other media, such as newspaper and magazine articles. Query results totaled 1,596 articles after
78 deduplication. Two authors reviewed abstracts and titles to include in the the full-text review round
79 and disagreements were adjudicated by a third author [initials deleted to maintain integrity of the
80 review process]. Next, during the full-text review round, two authors again reviewed full-text articles
81 for inclusion with a third author adjudicating disagreements. *Covidence*, a literature review
82 management software, was used to review articles during inclusion and exclusion steps

83 Then, two authors performed data extraction (TL,SP) using a data charting table. Data extracted
84 included: primary thesis or outcome measure (e.g. death by suicide, suicide attempt, suicidal ideation
85 or thoughts), date of publication, authors' country affiliation, type of publication, study design,
86 country of participants, tools used to ascertain outcome measures, and physician population
87 (specialties, career stage). While reviewing articles, authors used an open coding approach to tag
88 articles by key topics or themes (e.g. suicidal ideation, depression, prevention, substance use, etc.).
89 The aim was to inductively identify key themes across the published literature included in this
90 scoping review. During each subsequent round of review, tags could be added to articles. After all
91 articles were reviewed and tagged by two authors (TL,SP,CYAC), one of the authors (TL) re-
92 reviewed all articles to add tags until a point of saturation was reached and no further topic tags could
93 be added. Tags were then condensed into a core set of themes. These themes were assembled into a
94 framework based on their frequency of occurrence, resulting in a map of the most published themes
95 about physician suicide. Findings are summarized in narrative form.

96 **3 Results**

97 The 347 articles that met inclusion criteria (Figure 1) covered a broad range of publication types over
98 time and from countries worldwide. The earliest publications were editorials (Table 1), with the first
99 published in 1903 by an unknown author. Overall, 143 (41.2%) opinion articles were published,
100 suggesting an ongoing public dialogue about physician suicide in academic journals lasting over a
101 century. Of the remaining 204 (58.8%) articles, cross-sectional study design involving a survey was
102 the most commonly used study design. Of these, 13 described interventions intended to prevent
103 physician suicide. Such articles frequently introduced the paper by describing “a tragic case,” when
104 the death of one or more physicians by suicide stimulates the development or implementation of an
105 intervention (11).

106 Authors from 37 countries published articles on physician suicidal behaviors, including: the United
107 States, United Kingdom, Finland, Norway, Sweden, Italy, Japan, Canada, China, Denmark, Hungary,
108 Brazil, Egypt, Germany, Lebanon, Pakistan, Poland, Taiwan, Austria, Belgium, Bosnia and
109 Herzegovina, India, Iran, Malaysia, Nepal, New Zealand, Portugal, Serbia, South Korea, Spain,

Physician Suicide: A Scoping Review to Highlight Opportunities for Prevention

110 Thailand, Turkey and the United Arab Emirates. Some countries have only published opinion articles
111 about the subject, including Israel, Nigeria, and Pakistan. Six articles were opinion articles that
112 contained no information about country of origin.

113 3.1 Ascertaining Suicidal Behaviors

114 3.1.1 Estimating Suicide Incidence

115 Death by suicide was the only primary topic in 108 (31.1%) of all articles. Non-opinion articles
116 primarily sought to estimate epidemiology of suicidal behaviors among physician populations. In
117 other words, death by suicide was most often studied among attending physicians because of
118 availability of data on occupation and death, particularly in vital statistics or death certificates.
119 However, the tools used to perform such estimates varied. Deaths by suicide were most frequently
120 estimated based on 9th or 10th Revisions of the International Classification of Diseases (ICD-9 or
121 ICD-10) codes on death certificates. Other commonly used sources of data included membership
122 masterfiles from physician organizations or associations (12), published obituaries, and charts from
123 medical records or forensic reports (Table 2). These data are primarily limited by potential
124 undercoding. Undercoding can result from deaths being coded as accidental deaths, for example,
125 leading to underestimation of the actual incidence of suicides among physicians. In an editorial, one
126 author notes, “Suicide is a way to die and not a cause of death. And there are several means to this
127 end: the ICD-10 lists at least 31 different ways to perform a suicide” (13). Rimpela et al articulated
128 this in 1987 also: “Differentiation between suicide, accident, poisoning, and violence as a cause of
129 death is often difficult, and suicide might sometimes be falsely, even deliberately, classified as an
130 accident and even differently in different occupational groups” (14).

131 Suicides are typically reported as a *suicide mortality rate* (SMR) in epidemiologic literature, which is
132 the number of deaths by suicide per 100,000 person-years. A *suicide rate ratio* can be calculated by
133 dividing the SMR among physicians, or a subpopulation thereof, and dividing by a comparison
134 group, such as the general population. Despite these standardized manners of suicide reporting,
135 included papers showed inconsistencies in reporting, often reporting a *crude mortality rate*, which is
136 calculated by the absolute number of physician suicides divided by the number of years in a study
137 period, then reported per 100,000 physicians. For example, in 1968 Craig and Pitts counted 228
138 suicides among physicians, based on obituary materials collected by the Deaths Editor of the *Journal*
139 *of the American Medical Association*, between May 1965 and May 1967 (15). Combined with an
140 estimation of approximately 296,000 physicians in the U.S. at the time, this resulted in a *crude*
141 *annual suicide rate* of 38.4 per 100,000 physicians (15). Multiplying this crude annual suicide rate
142 and the U.S. physician population of approximately 953,000, which was reported by a 2016 census
143 from the Federation of State Medical Boards, leads to an estimate of 366 physician deaths by suicide
144 annually.

145 Underreporting undermines the accuracy of physician suicide incidence estimates using death
146 certificates, membership files, and medical charts. Surveys also can lead to underreporting. One study
147 surveyed the deans of 116 medical schools in the 1970s about medical student suicides; 88
148 respondents reported 52 medical student suicides between 1970 and 1978 (16). Another approach to
149 studying physician suicides is psychological autopsy, in which a psychological profile about a person
150 is constructed after their death. Time-intensive and not a standard practice, psychological autopsy
151 involves collecting information through interviews of relatives and healthcare professionals, along
152 with data from forensic examinations, police investigations, psychiatry, medical and social agency
153 records, and any other information available, such as suicide notes (17). Such an approach can
154 elucidate potential contributors to an individual’s death, providing detailed contextual information,

Physician Suicide: A Scoping Review to Highlight Opportunities for Prevention

155 their life circumstances, and how they managed such circumstances up until their death. However,
156 psychological autopsies are not systematically applied in the setting of deaths by suicide. Case
157 reports also may describe a psychological profile, in addition to medical and clinical aspects of the
158 case (10,17,18), but this was also infrequently published. In 2013, Gold et al examined data from the
159 U.S. National Violent Death Reporting System (NVDRS), which is a combination of information and
160 data from death certificates, coroner and medical examiner reports, toxicology reports, and law
161 enforcement reports (2), the only study to triangulate multiple data sources to estimate suicide
162 incidence. The wide variety of data sources and methods of estimation suggest that there is no
163 standard.

164 3.1.2 Suicide Clusters

165 *Suicide clusters* are suicides that occur near each other, typically with respect to time and geography.
166 *Suicide contagion* refers to spread of information about a suicide via media and other channels,
167 which can increase suicide risk in a community. Only three studies acknowledged these topics. Two
168 opinion papers described suicide clusters that occurred in a short time span and in a focused
169 geographic region, one in Winnipeg, Canada (19) and another cited suicides in Australia that had
170 been reported in news media (20). Both articles focused on intense or distressing working conditions
171 as important factors in the suicide deaths but did not elaborate further on suicide clustering. In fact,
172 the Canadian article, along with one other case series of physicians who died by suicide while on
173 probation in Oregon state (21), used the term “epidemic” rather than “clusters.” Nonetheless, all three
174 papers referred to the concepts of suicide clusters and suggest contagion, even though they do not use
175 these terms explicitly. These were articles were tagged with the public health theme.

176 Suicide clusters also appeared to follow physician subpopulations, although numbers were small in
177 such case series and opinion articles. Unexpected physician subpopulations included, for example,
178 immigrant physicians (22), physician pilots (23), and physicians who experienced war either as
179 victims or as wartime medics (24,25). In 2016, Bock et al describe a case series of 62 Hungarian
180 Jewish dermatologists during the Holocaust: some emigrated, some died during Nazi rule, and others
181 survived (24). Three of these dermatologists died by suicide, which was “very common among the
182 doctors [under the Nazi ordeal], especially those physicians of the older generation” (24). Another
183 unexpected analysis described the confusing ethical circumstances of physicians as terrorists (26).

184 3.1.3 Estimating Suicidal Ideation and Attempts

185 Overall, suicidal ideation was the second most studied thesis among articles included in this literature
186 review, especially suicidal ideation among medical students. To assess suicidal ideation and attempts,
187 surveys were most commonly used; overall, 61 cross-sectional survey studies were performed (Table
188 1). Validated surveys are available to assess suicidal ideation (Table 2), however, investigator-
189 developed items and surveys were also used. Only four studies compared physician subpopulations
190 between countries. In the Health and Organization among University Hospital Physicians in Europe
191 (HOUPE) study, investigators sought to compare suicidal thoughts and work-related stressors
192 between practicing physicians in Italy and Sweden (27–29). Another study compared lifetime
193 prevalence of suicidal thoughts among practicing physicians in Norway and Germany (30).

194 Suicide attempts in general were poorly studied in any physician subpopulation, but suicidal
195 behaviors among postgraduate trainees were the least studied of all, with resident physicians’
196 behaviors studied more than fellows. Among articles reviewed, only two validated tools, Paykel’s
197 Instrument and the Beck Hopelessness Scale, were identified that were specifically designed to assess

Physician Suicide: A Scoping Review to Highlight Opportunities for Prevention

198 suicide attempts; otherwise, investigators developed survey items to assess respondents' self-reported
199 attempts.

200 3.2 Physician-specific Risk Factors

201 3.2.1 Mental Health and Burnout

202 Physicians' risk factors for suicidal behaviors, especially mental health disorders, are among the most
203 common topics of study. Gold et al examined NVDRS data and identified certain risks unique to
204 physicians compared to non-physicians: physicians were more likely to have a job problem preceding
205 death by suicide, and a greater likelihood of known mental health disorders, yet no accompanying
206 increased likelihood of antidepressant therapy (2). Additional risk factors potentially include
207 professional setbacks prior to suicide death, such as facing complaints (21,31), feeling overloaded,
208 working long hours, or being unable to cope with job responsibilities (10), or experiencing disability
209 as a result of medical illness (17,23,32). Related to these conditions, physicians are also at high risk
210 of burnout, which has been found to be associated with suicidal ideation in U.S. medical students
211 (33) and Dutch residents (34), although no direct relationship between burnout and death by suicide
212 has been established. To assess these risk factors, a variety of validated questionnaires were used to
213 inquire about general health, burnout and stress, mental health (e.g. depression, anxiety or insomnia),
214 substance use including alcohol use, and other measures of career, work, personality, and other life
215 experiences (Table 2). Additionally, investigator-developed survey questions were also used, for
216 example, to assess attitudes towards suicidal behaviors of a peer.

217 Because the earliest publications about physician suicide suggested an increased incidence compared
218 to the general population, certain theories have been applied to attempt to explain the increased
219 suicide risk among physicians. For example, Fink-Miller applied the interpersonal psychological
220 theory of suicidal behavior (IPT) (35,36) to physician suicide. The IPT posits three necessary and
221 sufficient precursors to death by suicide: (1) *thwarted belongingness*, a feeling of disconnection with
222 others, (2) *perceived burdensomeness*, a miscalculation that one's death would relieve burdens on
223 others, and (3) *acquired capability*, habituation to previously provoked fear responses, including
224 losing the fear of pain involved in taking one's life. This can stem from repeated exposure to painful
225 or provocative stimuli, including events triggering second victimization, such as patients' poor
226 outcomes, death, and suffering. This can then lead to desensitization when exposed to death in
227 general. *Role strain* describes physician risks as a result of their direct work environment or
228 professional norms; a mismatch between social and institutional norms and the physician's roles can
229 manifest as an unrealistic expectation of perfect function at a maximum level of competence (37).
230 Professional self-image and identity, along with self-stigma, are also considered relevant mediating
231 themes (17,23,38).

232 Early studies of suicide rates by specialty suggested that psychiatry and anesthesiology had the
233 highest suicide rates (35). Indeed, these two specialties occurred most frequently in this scoping
234 literature review, followed by surgery or general surgery. However, the findings remain mixed due to
235 data limitations in ascertaining suicide rates as noted previously (39–41). Furthermore, no
236 explanations for the association have been offered other than a proffered but unstudied hypothesis
237 that some medical specialties may possess more acquired capability than others (36,42).

238 3.2.2 Specialized Knowledge and Access

239 The *access and knowledge hypothesis* is a commonly discussed risk factor for suicide death among
240 physicians. Physicians acquire specialized medical knowledge of the human body and have access to
241 the means (e.g. prescription drugs) that can cause lethal self-harm. Observational studies of means of

Physician Suicide: A Scoping Review to Highlight Opportunities for Prevention

242 suicide death suggest that firearm, prescription drug overdose, and hanging are among the most
243 common methods used by physicians (14,35,41), although this varies by country. Psychological
244 autopsies are consistent with the access and knowledge hypothesis. One set of psychological
245 autopsies in the United Kingdom examined 38 physician suicides, finding that 28 of the physicians
246 died by self-poisoning and 11 by self-injury (other than poisoning), as one physician used both
247 methods (10). In a Finnish psychological autopsy of 7 physician suicides, only 2 had previous suicide
248 attempts, suggesting that physicians may be more likely to cause self-harm leading to death by
249 suicide; in other words, physicians who die by suicide may not have had any prior suicide attempt,
250 which is risk factor in the general population (17). Self-treatment or self-prescription is also a
251 concerning contributor due to specialized access to controlled substances, as “medical doctors exploit
252 their profession for purpose of self-treatment” (17).

253 3.2.3 Personality Traits, Upbringing, and Cultural Context

254 Personality and life experience prior to medical training might also contribute to physician suicide
255 risk, although are poorly studied. In a prospective study of Norwegian medical students, the control
256 personality trait, or the degree of compulsiveness, was independently linked to suicidal ideation; and
257 more neuroticism, or the vulnerability personality trait, as a medical student independently predicted
258 more serious suicidal ideations and planning in the first two postgraduate years (9,43,44). Reality
259 weakness, more commonly associated with serious psychiatric pathology, predicted a transition from
260 suicide ideation to planning (9). Neuroticism and tendency towards perfection may even be traits
261 sought in potential medical trainees. One editorial speculates about the influence of adverse
262 childhood experiences on risk for physician suicide (45). One South Korean study found a more than
263 threefold risk of lifetime suicidal ideation, planning, and attempts among medical students who
264 experienced emotional abuse early in life, characterized by “a continuously cold and uncaring
265 parental attitude” (46). In China, medical students were surveyed about parental relationships and
266 parenting communication styles, hypothesizing that this could be a highly influential aspect of the
267 student’s character (47). The study found that for Chinese medical students, a good relationship with
268 parents was statistically significantly associated with less suicidal ideation, plans and attempts.

269 Some studies sought to identify risk factors unique to their cultural context. Researchers in the United
270 Arab Emirates collaborated with Eskin (48) to again assess medical students’ religiosity and their
271 attitudes towards suicide (49). In this study, investigators suggested that the Islamic faith may serve
272 as a protective factor against suicidal thoughts and death by suicide among their medical students. In
273 Pakistan, a study of suicidal ideation among medical students included religion as a demographic
274 characteristic but did not otherwise include religion in further analyses (50). Among opinion articles,
275 certain conceptualizations of suicide also varied. For example, in one commentary from Japan, two
276 concepts directly link overwork with death: *karoshi* (death due to overwork) and *karojisatsu* (suicide
277 due to overwork) are considered causes of death in the Japanese culture (51) but nowhere else in the
278 world.

279 3.2.4 Gender

280 Early studies in the 1970s and earlier explicitly excluded female and minority physicians (43,52,53).
281 Results published in 1999 from the Women Physicians’ Health Study, which surveyed a sample of
282 women physicians from the American Medical Association masterfile (54), described prior studies
283 that reported an odds ratio as high as 4 for women physician suicides compared to other categories of
284 women but that such studies were based on small numbers of suicide deaths. In 2004, Schernhammer
285 performed a systematic review and meta-analysis, concluding that the suicide rate ratio for women
286 physicians was 2.27 compared to the general women population, and 1.41 for male physicians

Physician Suicide: A Scoping Review to Highlight Opportunities for Prevention

287 compared to the general male population (1). The 1999 study found that women physicians had
288 similar rates of depression compared to the general population but had lower numbers of suicide
289 attempts (54); the authors postulate that women physicians may have less suicidal intent or a higher
290 rate of completion than the general population, although the study's scope did not include these
291 outcomes. In 2013, a Polish study of perimenopausal female physicians examined sociodemographic
292 and lifestyle variables' relationship to participants' subjective sense of health, including suicidal
293 ideation. Eight of 221 participants reported suicidal thoughts, which was statistically significantly
294 correlated with poorer subjective sense of health (55). Another study in Pakistan appeared to show no
295 gender difference in terms of rates of suicidal ideation among medical students (56). Little data is
296 known on suicide among physicians of gender minorities, as only one perspective piece written by a
297 nurse who wrote about her transgender child who died by suicide (57).

298 3.3 Themes in Physician Suicide Literature

299 This scoping literature review revealed several themes in physician suicide literature, with greatest
300 attention to identifying risk factors, such as mental health. Culture of practice and context of suicide,
301 which include, for example, mental health stigma, physician attitudes towards suicide, and job
302 conflicts, also were subjects of increased focus. These and the remaining themes identified are
303 illustrated in Figure 2, where the most common themes are positioned at the broadest (top) level of an
304 inverted pyramid. With each successive level of the inverted pyramid, fewer papers describe such
305 issues. We chose an inverted pyramid to illustrate how the weight of the risk factors for physician
306 suicides are balancing precariously over the vertex, where less attention on postvention and public
307 health initiatives for surveillance and prevention. This imbalance quickly identifies potential areas for
308 further work. Themes such as suicide as a public health issue, postvention, and legal issues were far
309 less studied than others.

310 In the second level of the framework are epidemiologic and demographic focuses for study, which
311 were previously described in section 3.2. Along with these subjects are a relatively lesser focus on
312 substance use, compared to other risk factors such as mental health, and on developing educational
313 curricula to address knowledge gaps about suicide and its prevention. Wellness is an increasingly
314 popular topic for publication on this level of the framework. In the third level of the framework are
315 prevention approaches. Thirteen articles described interventions with a primary aim of preventing
316 physician suicides. Frequently, programs were implemented as an organizational response to a
317 physician suicide. Five interventions implemented the AFSP's Interactive Screening Program for
318 suicide prevention (58,59) as a component of a larger initiative to promote physician well-being;
319 three of the five came from the same institution (60–62). Only one of 13 was a randomized controlled
320 trial of a web-based screening program (63).

321 Treatments and responses to physician suicide were discussed as frequently as prevention; treatments
322 and responses differed because treatments tended to focus on individual physician treatment for
323 suicidal behaviors or related mental health disorders, and responses tended to focus on small group,
324 physician health program, or medical board responses to individual circumstances. For example,
325 Young et al described the difficult grieving process for a healthcare team after the death a physician
326 (64). Patients were told that the physician who had died "was not available," trust between staff and
327 administrators eroded, morale decreased, and grieving, guilt and other negative consequences
328 remained unaddressed until six weeks after the physicians' death (64). The process of facilitating a
329 normal grieving process after a suicide death has occurred requires active planning, called
330 *postvention*. In another study by Kaltreider et al, 20 medical students were interviewed after the death
331 of a classmate by suicide (65). This qualitative study found that students experienced intense,

Physician Suicide: A Scoping Review to Highlight Opportunities for Prevention

332 intrusive, and persistent thoughts and emotions relating to their classmate's death, sometimes lasting
333 for months. Proximity to the site of the death, prior exposure to another suicide previously, or
334 familiarity with depression in themselves or family seemed to increase these effects.

335 Legal and policy issues are increasingly recognized as affecting physician health and well-being, and
336 appear in the third and fourth levels of Figure 2. Physicians may avoid seeking mental health
337 treatment, avoid self-report, and self-treat mental health and other health issues (66,67), out of fear of
338 reputational damage or concern about perceived weakness or impairment (68). Licensure application
339 questions could be improved (68) and compassionate, confidential assistance programs, such as one
340 implemented in the United Kingdom in 2010, could offer bespoke services to physicians who might
341 be considered at risk of suicide (67). In 2015, the UK's General Medical Council was recommended
342 to fund a pilot program that would include developing a national support service for doctors (69).
343 However, no literature was found to describe such policies in other countries.

344 Only three articles describe suicide clustering and suicide contagion, which are unique public health
345 concepts pertaining to suicide (19–21). However, no further follow-up or other literature regarding
346 these suicide clusters were found in this scoping review. As a result, the themes of postvention and
347 public health approaches to physician suicide both were at the vertex (bottom) of the inverted
348 pyramid.

349 **4 Discussion**

350 As a scoping literature review, this review did not include a quality assessment of quantitative
351 evidence from included papers nor did it perform a meta-analysis or any statistical comparisons of
352 published evidence, which would be characteristic of a systematic review (6). More papers on
353 physician suicide have been published over the last two decades than before. This follows an overall
354 trend in published literature on physician well-being and may also reflect growing public recognition
355 of and decreasing stigma relating to suicide. Furthermore, the proportion of opinion articles
356 published is lower in the recent past compared to previously, indicating growing application of
357 contemporary statistical and scientific methods to the study of physician suicide. Nonetheless, themes
358 identified reveal opportunities for further work. The inverted pyramid framework (Figure 2) suggests
359 that there is a dearth of work on examining physician suicide using typical public health approaches
360 to investigate suicide clusters.

361 Figure 3 offers a proposed framework that highlights priorities for continued work on physician
362 suicide. This framework highlights the potential for developing an organized public health approach
363 to preventing physician suicide. The pyramid's base identifies areas for immediate, targeted actions,
364 forming the foundation for the following recommendations for action:

- 365 • Mandatory reporting, an approach used for workplace injury reporting, which could
366 improve surveillance of physician deaths by suicide (prevention);
- 367 • Identification of minimum acceptable community standards of validated instruments
368 to assess suicidal ideation and attempts (prevention, public health);
- 369 • Development and implementation of evidence-based screening and service provision
370 for suicide risk factors (58–63) (prevention);
- 371 • Development of early warning systems, like those used to monitor infectious disease
372 outbreaks, to signal suicide clusters and contagion (public health);
- 373 • Implementation and dissemination of best practices, especially regarding postvention or
374 additional directed interventions (postvention);

Physician Suicide: A Scoping Review to Highlight Opportunities for Prevention

- 375 • Increase education in the healthcare community about suicide warning signs and
376 prevention (education, wellness);
377 • Standardized education in the medical community about appropriate reporting on
378 suicides to prevent suicide contagion (education);
379 • Reduction of barriers to help-seeking behavior, reduce systematic stigma in licensing
380 and investigative processes (policy issues, legal issues).

381 Higher levels in Figure 3 include continued study of persistent risk factors, contextual and cultural
382 challenges, social factors like family, and health inequities resulting from gender, immigrant, or other
383 minority status, among other concerns. Currently available information is insufficient to draw
384 conclusions about physician subgroups or their cultural or health system contexts. Such information
385 on understudied physician subgroups could better inform future revisions of public health,
386 prevention, and postvention programs to include diversity-sensitive suicide prevention approaches.

387 The strengths of this scoping literature review are its breadth and inclusiveness in examining multiple
388 types of published literature in scholarly journals. However, due to the volume of citations generated
389 by the searches, we excluded grey literature (e.g. conference proceedings, poster presentations, etc.)
390 and snowballing of references was not performed. Additionally, physician suicide involves multiple
391 disciplines, and searching additional electronic databases of peer-reviewed and non-peer-reviewed
392 literature may be appropriate for future updates of such a literature review. Finally, additional articles
393 have been published on physician suicide since the end of the search period of April 2018. Excluding
394 non-English language publications may have led to overrepresentation of countries where English is
395 the official language. Among the 46 non-English language papers excluded (Figure 1), potentially
396 relevant papers were published in German, Spanish, Dutch, Finnish, Japanese, Chinese, French,
397 Swedish, and Hungarian, which could reveal relevant themes in physician suicide, including cultural
398 or health system context. Future studies could identify opportunities for cross-disciplinary and cross-
399 cultural learning and suicide prevention.

400 **5 Conclusion**

401 This scoping review offers a landscape view of physician suicide literature and opportunities for
402 further work on physician suicide prevention. Interventions are needed at multiple levels to mitigate
403 the risks of physician suicide, which could begin with an organized public health approach. As a part
404 of such an approach, consistency and reliability of data and information about physician suicides
405 could be improved. Data limitations partly contribute to these issues. For example, annual rates of
406 physician suicide reported and quoted may result from extrapolated estimates from old data, such as
407 those collected by Craig and Pitts in 1968 (15). Reliable and trackable data and information can
408 provide more continuously updated insights into actual suicide mortality rate ratios of physician
409 suicide compared to other populations (70). Also, systems could be developed to better monitor
410 physician suicides, offer early warnings of possible suicide clusters or contagion, and may improve
411 investigation and interventions for the benefit of physicians' and public health. Physician suicide
412 should be approached as a public health issue and as a shared responsibility between individuals and
413 institutions to prevent physician deaths by suicide.

414 **6 Author Contributions**

415 TIL, SP, and CYAC designed the study and performed study selection. RS performed the literature
416 search. TIL and SP extracted data, TIL performed computational analyses, and TIL, SP, and CYAC
417 interpreted the data. TIL drafted the manuscript, except for the Methods section which was drafted by

Physician Suicide: A Scoping Review to Highlight Opportunities for Prevention

418 RS, and the entire manuscript was produced with critical revisions and important intellectual content
419 from all authors.

420 **7 Acknowledgments**

421 The authors wish to acknowledge Dr. Christine Moutier and Dr. Srijan Sen for their critical review
422 and feedback on the manuscript, as well as Dr. Matthew Goldberg for his early contributions to the
423 background and initial design considerations for this review.

Fig. 1 PRISMA diagram of study selection for inclusion

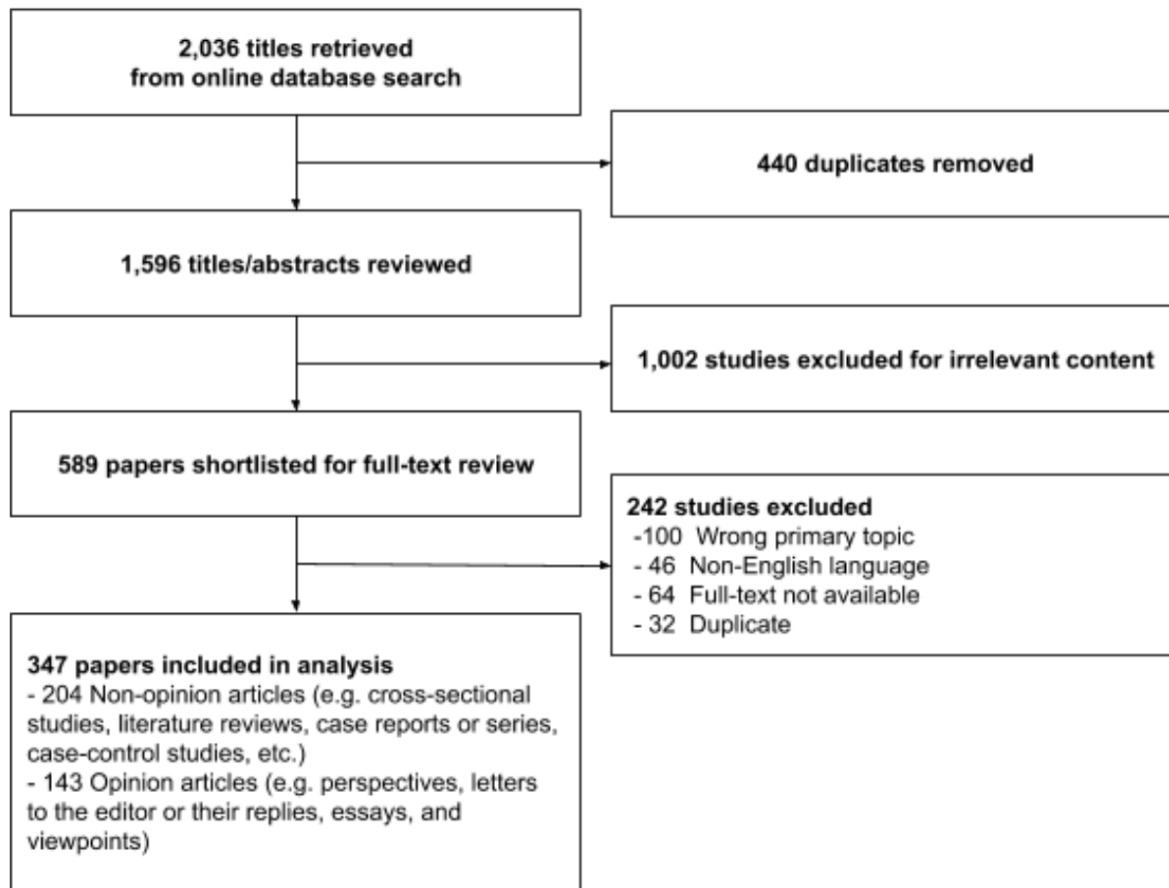

Table 1. Article characteristics from scoping review of literature on physician suicide, 1903-2018

| Publication date range | No. (%) of non-opinion articles | No. (%) of opinion articles |
|-------------------------------|----------------------------------------|------------------------------------|
| 1900-1919 | 0 | 1 (0.7%) |
| 1920-1949 | 0 | 1 (0.7%) |
| 1950-1959 | 0 | 0 |
| 1960-1969 | 5 (2.4%) | 9 (6.3%) |
| 1970-1979 | 24 (11.7%) | 19 (13.3%) |
| 1980-1989 | 20 (9.8%) | 18 (12.7%) |
| 1990-1999 | 26 (12.7%) | 14 (9.9%) |
| 2000-2009 | 42 (20.5%) | 37 (26.1%) |
| 2010-2018 | 88 (42.9%) | 43 (30.3%) |

| Study design or publication type | No. (%) of non-opinion articles | No. (%) of opinion articles |
|-----------------------------------------|----------------------------------------|------------------------------------|
| Cross-sectional studies | 85 (41.5%) | N/A |
| Survey-based | 63 | |
| Review | 34 (16.6%) | |
| Narrative | 30 | |
| Case report or case series | 22 (10.7%) | |
| Case-control | 19 (9.3%) | |
| Cohort studies | 14 (6.8%) | |
| Intervention† | 13 (6.3%) | |
| Other†† | 18 (8.8%) | |

†Publications about an intervention at minimum describe the intervention.

††Other study designs included: qualitative studies or psychological autopsy (n=8), validation or evaluation of a survey instrument or screening question (3), news coverage (4), poetry (1), a discussion guide (1), or a correction (1).

Table 2 Methods of ascertainment of suicidal behaviors and related risk factors, for 204 non-opinion publications

Methods of ascertainment

Suicide death

Death certificates (vital statistics by U.S. state or non-U.S. country)
Forensic, pathology, or autopsy reports, e.g. from a medical examiner's office
Medical chart reviews of physician patients
Professional membership masterfiles
Obituaries published in journals (e.g. *JAMA*)
Family confirmation or interviews

Suicide attempt

Paykel's Instrument (assesses suicidal ideation and suicide attempts)
Beck Hopelessness Scale
Investigator-developed question(s) or questionnaire

Suicidal thoughts or ideation

Patient Health Questionnaire 9
Beck Scale for Suicidal Ideation
Acquired Capability for Suicide Scale
Self-harm Behavior Questionnaire
Suicidal Behaviors Questionnaire
Investigator-developed question(s) or questionnaire
