Abstract

Background

Despite remarkable advancements in reducing maternal and neonatal mortality, maternal delivery at home continue to pose a significant public health challenge in many low- and middle-income countries including Bangladesh. Although the incidence of maternal delivery at home has declined substantially over the past decade, pronounced disparities persist across geographic, socioeconomic, and demographic dimensions in Bangladesh. A nuanced understanding of the spatiotemporal patterns in the prevalence and determinants of maternal delivery at home is essential for designing targeted interventions. This study investigates the spatial variations in the prevalence and determinants of maternal delivery at home in Bangladesh over time.

Methods

We analyzed data from the Multiple Indicator Cluster Survey conducted in 2012–13 and 2019 as well as the Bangladesh Demographic and Health Survey conducted in 2022 to compare district-level estimates for maternal delivery at home. Descriptive statistics and multivariable logistic regression were employed to assess the prevalence and determinants of maternal delivery at home.

Results

The prevalence of maternal delivery at home declined from 68.1% in 2012-13 to 34.9% in 2022 in Bangladesh. However, significant geographical disparities persist. The prevalence of maternal delivery at home was higher in the Barisal (48.9%), Chattogram, Sylhet, and Mymensingh divisions. The lowest rates were observed in Dhaka and Khulna. At the district level, remote areas such as Bandarban, Rangamati (55.9%), and Bhola presented higher rates of home deliveries. Multivariable logistic regression analysis identified several significant

predictors of home delivery. Compared with those with secondary or higher education, women with no formal education were more likely to deliver at home. Limited ANC visits (≤3 visits) significantly increased the likelihood of home birth. Rural residence, lower household wealth, multiparity (≥3 children), and lack of media exposure were also significant determinants of home delivery.

Conclusions

Despite progress in reducing home deliveries, persistent geographic and socioeconomic disparities highlight the need for targeted interventions. Strengthening healthcare infrastructure in underserved regions, improving maternal health awareness, increasing ANC utilization, and addressing financial barriers through subsidies and incentive programs can further reduce the number of home births. Future research should explore the influence of cultural and religious factors to develop context-specific policies that promote equitable access to facility-based childbirth.

Keywords: Maternal delivery, spatiotemporal variations, socioeconomic disparities, determinants, Bangladesh.

Introduction

Despite a 40% reduction in the global maternal mortality ratio (MMR)- from 328 deaths per 100,000 live births in 2000 to 197 in 2023- over 90% of all maternal deaths continue to occur in low- and lower-middle-income countries [1] . South Asia remains a critical contributor, accounting for nearly one-quarter of global maternal fatalities [2]. As a prominent example, Bangladesh, a lower-middle-income country in South Asia, has made commendable progress in reducing its MMR from 412 deaths per 100,000 live births in 1976 to 123 in 2020 [3]. This progress has been accompanied by significant scale-up in key maternal health interventions, including antenatal care (4+ visits) from 17% in 2004 to 41% in 2022, facility-based delivery from 10% in 2004 to 65% in 2022, skilled birth attendance from 23% in 2007 to 70% in 2022, and postnatal care (by medically trained providers within 48 hours) from 16% in 2004 to 55% in 2022 [4]. Despite these advances, the gains have been unevenly distributed across geographic regions and socioeconomic strata, resulting in persistent disparities in maternal health outcomes. Consequently, Bangladesh remains off track to meet the Sustainable Development Goal target (SDG 3.1), which targets an MMR of fewer than 70 deaths per 100,000 live births by 2030 [5].

To accelerate the progress toward this ambitious goal, there is an urgent need to improve emergency obstetric services and minimize the incidence of maternal delivery at home, which are associated with preventable maternal and neonatal mortality. Globally, maternal delivery at home accounted for an estimated 287,000 maternal and 2.4 million newborn deaths in 2020 alone [6,7]. A study from Nigeria found that non-institutional delivery (delivery outside health facilities, often by unskilled attendants) was associated with a 79.2% chance of maternal death among the cases studied [8]. In Bangladesh, more than one-third of all deliveries still occur at home, with marked regional disparities across administrative divisions [4] Reducing home deliveries is, therefore, a critical public health priority to advance equity and reduce mortality and neonatal mortality [9–11]Maternal delivery at home is influenced by a complex interplay

of sociodemographic, economic, cultural, and health system factors. Key factors include maternal education, quantity of antenatal care visits, parity, household wealth, religion, and geographic accessibility to healthcare facilities [12–14]. In addition, entrenched poverty, traditional and religious norms, poor transportation infrastructure, and the limited autonomy among women in decision-making further exacerbate the preference for delivery at home [15]. Other factors such as low maternal and paternal education, advanced maternal age, multiparity, and low wealth status also contribute to increased home delivery practices [16]. Fear of cesarean sections, perceptions of poor quality of care, and the lack of female doctors also play substantial roles in influencing delivery preferences [15].

According to the availability, accessibility, acceptability, and quality (AAAQ) framework, both supply-side (e.g. healthcare infrastructure and provider availability) and demand-side (e.g. household-level barriers and perceptions) factors must be addressed to reduce maternal delivery at home [17]. While individual and household-level determinants have been widely studied, health system constraints- especially at the subnational level- remain largely underexplored in the context of Bangladesh. Identifying subnational areas (here district in Bangladesh) with persistently high rates of maternal delivery at home is essential for designing and implementing evidence-based maternal health interventions. However, limited research has assessed the temporal trends and geographic distribution of maternal delivery at home in Bangladesh [18–20] Moreover, little is known about how associated factors of maternal delivery at home vary over time across urban and rural settings. To our knowledge, no prior study has comprehensively investigated subnational spatiotemporal variations in maternal delivery at home or explored the evolving determinants of this practice.

Therefore, we aimed to investigate district-level spatiotemporal patterns of maternal delivery at home and analyze the temporal dynamics of associated factors in urban and rural areas in

Bangladesh. The findings will inform targeted, context-specific policies and support the implementation of effective maternal health interventions.

Materials and Methods

Data Sources

This study utilized secondary data derived from three nationally representative, population-based cross-sectional surveys: Multiple Indicator Cluster Survey (MICS) conducted in 2012–13 and 2019, and the Bangladesh Demographic and Health Survey (BDHS) conducted in 2022. The MICS, implemented by the Bangladesh Bureau of Statistics (BBS) with technical and financial support from the United Nations International Children's Emergency Fund (UNICEF), provides comprehensive data on household characteristics and maternal and child health indicators at the district level. The BDHS, administered under the authority of the National Institute of Population Research and Training (NIPORT), Medical Education and Family Welfare Division, Ministry of Health and Family Welfare (MOHFW), offers vital demographic and health statistics, including district-level estimates for the first time in 2022.

Sampling Design and Sample Size

Both the MICS and BDHS employed a uniform methodology to ensure national representativeness. Detailed methodological descriptions are available in the respective technical reports [4,21,22]. Briefly, the MICS applied a multistage stratified cluster sampling strategy, covering all 64 administrative districts of Bangladesh. Each district was stratified into urban and rural areas. Enumeration areas (EAs) were selected using the probability proportional to size (PPS) method within these strata. From each selected EA, 20 households were systematically sampled [23,24]The MICS sampled a total of 55,120 in 2012-2013 and 64,400 households in 2019, of 51,895 and 61,242 were successfully interviewed, with response rates of 98.5% and 99.4%, respectively. After excluding respondents with no delivery history or

missing birth outcome data, the final analytical sample included 7795 and 9284 women aged 15-49 years with a history of childbirth in 2012-2013 and 2019 respectively.

The BDHS 2022 utilized a two-stage stratified sampling strategy based on the 2011 Population Census. In the first stage, 675 EAs were selected (237 urban and 438 rural) using PPS sampling. In the second stage, 45 households were systematically selected from each EA to ensure adequate representation across residence types [25]. In 2022, the final response rate of BDHS was 99.6%, with 30,330 households selected and 30,018 households interviewed. The final analytical sample from BDHS 2022 consisted of 3,691 women of reproductive age (15–49 years) with recent birth histories.

Outcome Variable

The main outcome variable for this study was maternal delivery at home, defined dichotomously. Deliveries occurring at the respondent's home were coded as "1" (maternal delivery at home), and those occurring at any health facility were coded as "0".

Explanatory Variables

A total of 13 independent variables were selected on an extensive review of previous literature [13,26,27], capturing individual-, household-, and community-level determinants. Individual-level factors included women's age, education (no education, primary, secondary, and higher), number of antenatal care (ANC) visits (none, 1, 2, 3, and ≥4), parity (1–2, ≥3), media exposure, religion (Non-Muslim, Muslim), husband's age, and spousal age gap (≤5 years, 6–9 years, and more than 9 years). Household-level factors included education of household's head, household size and household's socioeconomic status. The community-level factors encompassed administrative division and place of residence (urban or rural). Socioeconomic status was assessed using the wealth index, constructed via principal component analysis (PCA) as

155 provided in MICS and BDHS datasets. Households were classified into five quintiles: poorest,
156 poorer, middle, richer, and richest [4,21,22].

157 ***Statistical analysis***

158 The data were analyzed via Stata version 17.0 (StataCorp, College Station, Texas, USA),
159 whereas data visualization was performed via R version 4.3.0. To account for the complex
160 survey design, we incorporated primary sampling units (PSUs) and strata and applied sampling
161 weights to ensure representativeness. The Stata "svyset" command was used to adjust for the
162 survey design [28], and all analyses adhered to the STROBE cross-sectional reporting
163 guidelines [29].

164 Descriptive statistics were used to summarize the characteristics of the study population, which
165 were reported as frequencies and proportions in percentages. We conducted bivariate analysis
166 using the Chi-square test to assess associations between the explanatory variables and the
167 outcome variable. We employed simple binary logistic regression analysis to estimate crude
168 odds ratios (ORs) with 95% CIs for each explanatory variables in the unadjusted analysis.
169 Variables that were statistically significant in the simple logistic regression models were
170 subsequently included in the multiple logistic regression model to estimate adjusted odds ratios
171 (AORs) with their respective 95% CIs. Statistical significance was determined at the 5% level
172 (p-value <0.05).

173 To account for the complex survey design, we applied the "svyset" command in Stata,
174 incorporating sampling weights, strata and primary sampling units (PSUs). All the analyses
175 were done using the "svy" prefix to ensure design-based estimates and inference [28]. The study
176 adhered to the STROBE guidelines for reporting cross-sectional studies [29]. Spatial analysis
177 was conducted using district-level choropleth maps to visualize geographic disparities in
178 maternal delivery at home. We used Stata version 17.0 (StataCorp, College Station, Texas,

USA) for data analysis, R version 4.3.0 for data visualization and ArcGIS version 10.8 for spatial mapping.

Ethical Consideration

This study utilized deidentified secondary data obtained from the UNICEF (https://mics.unicef.org/surveys) and DHS (https://www.dhsprogram.com/data/available-datasets.cfm) websites. Since the data were publicly available and did not contain any personally identifiable information, ethical approval was not needed. All participants provided informed consent, and the original surveys were carried out in accordance with ethical standards and approved by the appropriate institutional review boards.

Results

Sample characteristics

Across all survey years, approximately one-third of women were aged 20-24 years (33.6% in 2012-13, 32.2% in 2019, and 33.8% in 2022). Educational attainment demonstrated a positive trend over time, the proportion of women completing higher education increased from 12.4% in 2012 to 18.5% in 2022. Nearly nine in 10 women were Muslim (89.2% in 2012, 90.4% in 2019 and 92.7% in 2022). Media exposure declined slightly over the years, from 76.6% in 2012 to 66.3% in 2022. Utilization of ANC services improved, with the proportion of women receiving at least four ANC increased from 22.7% in 2012 to 40.5% in 2022. Fertility pattern showed that majority of women had 1–2 children, increasing from 65.6% in 2012 to 71.9% in 2022. The proportion of households headed by individuals with no education accounted for 56.2% in 2012, 30.3% in 2019 and 15.5% in 2022. The proportion of women in the poorest wealth quintile declined from 28.3% in 2012 to 20.2% in 2022. Household size remained relatively stable, with approximately two-thirds of women living in households comprising five or more members (65.6% in 2012-13, 63% in 2019 and 69.5% in 2022). Most women resided

203 in rural areas (83.8% in 2012, 80.9% in 2019 and 73% in 2022), and the Dhaka division

204 consistently had the highest representation across survey years (**Table 1**).

Spatial variations in maternal delivery at home

In Bangladesh, the prevalence of maternal delivery at home exhibited a marked decline over the past decade, decreasing from 68.1% [66.0-70.0%] in 2012-2013 to 46.4% [45.0-48.0%] in 2019 and 34.9% [32.0-37.0%] in 2022. Regional variation was evident, with Khulna Division demonstrating the lowest prevalence of maternal delivery at home across all years. In contrast, Barishal had the highest prevalence in 2012-13 and 2022, followed by the Sylhet division (**Figure 1**). Although regional variations were evident, district-level disparities in maternal delivery at home were more pronounced (**Table S1 and Figure 2**). In 2022, the prevalence of maternal delivery at home was >50% in 14 of 64 districts. The highest prevalence was observed in Gopalganj (68.8%), Khagrachhari (68.5%), and Lalmonirhat (66.3%), while the lowest was reported in Bandarban (0%), Chuadanga (0%), and Kushtia (6.5%). In 2012, home-based maternal delivery was most prevalent in hill tract districts such as Bandarban (97.2%) and Rangamati (88.6%), and in haor/coastal districts including Sunamganj (89.3%), Noakhali (88.1%), and Patuakhali (88.0%). By 2019, the burden remained high in hill districts-84.6% in Bandarban, 73.0% in Rangamati, and 76.1% in Khagrachhari. Despite a declining national trend, hill tract and northeastern districts had persistently high prevalence of maternal delivery at home.

Figure 1: National and divisional estimates of maternal delivery at home in Bangladesh, 2012-2022

Figure 2: Spatial distribution of home delivery in Bangladesh, 2012--2022

Subpopulation-level variations in maternal delivery at home

Despite national and subnational reduction, maternal delivery at home remained common among women aged 35-49 years, although the prevalence in this subgroup declined disproportionately from 79.1% in 2012-2013 to 49.1% in 2022. Women with no formal education consistently showed the highest prevalence of maternal delivery at home (87.5% in 2012-2013, 75.6% in 2019 and 55.7% in 2022), in contrast to women with higher education, whose prevalence fell from 32.2% to 12.6% over the same period. Muslim women persistently reported higher percentage of maternal delivery at home than non-Muslim women (68.9% vs 58.9% in 2012-2013, 47.5% vs 34.1% in 2019 and 36.4% vs 16.1% in 2022). No media exposure was also associated with a higher prevalence of maternal delivery at home, though the prevalence declined notably from 78.3% in 2012 to 51.6% in 2022. Women receiving four or more ANC visits had significantly lower prevalence of maternal delivery at home than those receiving none (38.6% vs 91.1% in 2012, 23.9% vs 80.5% in 2019 and 19.2% vs 76.3% in 2022). Higher parity (3+ children) was associated with increased maternal delivery at home relative to lower parity (1-2 children) over years (81.0% vs 61.8% in 2012, 60.9% vs 39.9% in 2019, and 50.1% vs 28.9% in 2022). Furthermore, women of households headed by individuals with no formal education, those from the poorest wealth quintile, rural residents exhibited

consistently higher prevalence of home-based maternal delivery. No significant differences in the prevalence of maternal delivery at home were observed in 2022 based on partner's current age, spousal age gap or household size (**Table 2**).

Determinants of maternal delivery at home

In multivariable analyses, women's religious affiliation, ANC utilization, parity, household head's educational attainment, household wealth status, and administrative division were consistently associated with the likelihood of home delivery across survey years. Muslim women exhibited significantly higher odds of maternal delivery at home compared to non-Muslim women, with the association strengthening over time- most notably in 2022 (AOR 3.20, 95% CI 1.99-5.14), relative to 2019 (AOR 1.99, 95% CI 1.60-2.47) and 2012-2013 (AOR 1.36, 95% CI 1.02-1.82). A clear inverse relationship was observed between ANC visit frequency and home delivery; women with four or more ANC visits had substantially lower odds of home delivery compared to those with no ANC visits, with similar magnitudes across all survey years (2012-13: AOR 0.16, 95% CI 0.12-0.20; 2019: AOR 0.17, 95% CI 0.14-0.20; 2022: AOR 0.16, 95% CI 0.11-0.23). Higher parity (≥3 children) was consistently associated with increased odds of maternal delivery at home (2012-13: AOR 1.73, 95% CI 1.25-2.39; 2019: AOR 1.73, 95% CI 1.46-2.05; 2022: AOR 1.81, 95% CI 1.40-2.35). Women residing in households led by individuals with higher educational attainment were significantly less likely to deliver at home compared to those in households headed by individuals with no formal education (2012-13: AOR 0.65, 95% CI 0.50-0.86; 2019: AOR 0.65, 95% CI 0.51-0.82; 2022: AOR 0.50, 95% CI 0.36-0.71). A strong socioeconomic gradient was evident, wherein women from the poorest households had markedly higher odds of maternal delivery at home compared to those from the

wealthiest households (2012-13: AOR 2.54, 95% CI 1.80-3.59; 2019: AOR 3.34, 95% CI 2.59-4.30; 2022: AOR 2.84, 95% CI 1.86-4.33). Regionally, women from Khulna division consistently showed lower odds of home delivery (2012-13: AOR 0.61, 95% CI 0.48-0.78; 2019: AOR 0.59, 95% CI 0.47-0.74; 2022: AOR 0.38, 95% CI 0.26-0.56). Furthermore, women exposed to media were less likely than their counterparts for maternal delivery at home in recent years (2019: AOR 0.78, 95% CI 0.68-0.89; 2022: AOR 0.75, 95% CI 0.61-0.92). In contrast, maternal age, educational attainment, and urban-rural residence were significantly associated with maternal delivery at home in earlier survey rounds (2012–2013 and 2019), but their effects were less prominent in 2022 (**Figure 3 and Table S2**).

Figure 3: Determinants of maternal delivery at home in Bangladesh, 2012-2022

The frequency of ANC visits and household wealth were consistently associated with maternal delivery at home across both urban and rural settings. Specifically, women who attended four or more ANC visits and those from the poorest households demonstrated a lower likelihood of maternal delivery at home compared to their counterparts. In rural areas, maternal delivery at home was significantly associated over time with religious affiliation, media exposure, parity, and the educational attainment of the household head. However, these associations were not consistently observed among urban women across survey periods (**Table 3**).

Discussion

This study provides important insights into the changing landscape and persistent disparities of maternal delivery at home in Bangladesh over the past decade. Although the national prevalence of maternal delivery at home has declined markedly from 68.0% in 2012 to 34.9% in 2022, our findings reveal that this progress is not uniform across the country. Maternal delivery at home varied substantially at the district level, with the hill track districts-such as Rangamati, Bandarban, and Khagrachari-continuing to report rates exceeding 60% in 2022, nearly double the national average. These geographic inequities highlight the limited reach of facility-based delivery interventions in remote and marginalized areas, where barriers such as poor infrastructure, entrenched cultural preferences, and restricted access to healthcare persist despite national improvements.

Our analysis also identified several key factors associated with maternal delivery at home, including religion, number of antenatal care (ANC) visits, parity, education of the household head, household wealth, and administrative division. Muslim women were more likely to have maternal delivery at home compared to non-Muslims. Women with fewer than four ANC visits, those with higher parity, and those from the poorest households were significantly more likely to experience maternal delivery at home. Importantly, our findings show that the determinants of maternal delivery at home are not consistent between urban and rural areas, suggesting that context-specific, modifiable factors must be considered when designing interventions. While household wealth, ANC visits, and parity were the strongest predictors in rural settings, in urban areas, religion and the education level of the household head played a more prominent role. This urban-rural divergence indicates that interventions must be tailored to the unique drivers of maternal delivery at home in each setting-

prioritizing economic empowerment and improved ANC access in rural areas, and focusing on education and cultural engagement in urban contexts.

Our findings reveal substantial division- and district-level differences in home delivery rates. Home delivery remained particularly prevalent in the Barisal, Sylhet, and Mymensingh divisions, where approximately half of the deliveries still occurred at home. These regions have historically faced challenges in healthcare infrastructure, literacy rates, and accessibility, which may contribute to the sustained high prevalence of home deliveries [30]. Previous studies have similarly highlighted that healthcare services in the Mymensingh and Barisal divisions are inadequate, which may further explain the persistence of home deliveries in these areas [31,32]. Similar findings were also reported in different countries, which reported that home delivery rates were typically higher in less developed areas with poor transportation and access to healthcare [33,34]. At the district level, home deliveries were most common in peripheral and remote areas such as Bandarban, Rangamati, Khagrachari, Bhola, and Habiganj. This pattern aligns with findings from Nepal, where home delivery rates were notably higher in mountainous regions due to limited access to healthcare facilities [35].

One important factor influencing home delivery was found to be educational attainment. Compared with women without formal education, those with greater levels of education had a much lower likelihood of giving birth at home. This result is in line with other research from several nations, indicating that education is crucial in influencing maternal healthcare choices [36,37]. Awareness and knowledge might be the main reasons for this type of scenario, as women with lower levels of education may possess limited awareness regarding maternal healthcare facilities and the advantages of in-facility deliveries [37–39]. Education empowers women to efficiently navigate

healthcare institutions and make informed decisions about their health [37]. While the gap in home delivery rates between educated and less educated women has narrowed over time, further efforts are required to ensure universal access to facility-based deliveries, particularly among disadvantaged groups.

Home delivery rates are strongly impacted by the household head's educational attainment in addition to the mother's education. The more educated the household head was, the less likely the woman was to give birth at home. According to a Nigerian study, households with educated heads spent more money on healthcare, which increased the rates of institutional delivery [40]. Another study in Bangladesh revealed that a lower education level of household heads decreases maternal healthcare utilization in Bangladesh [41]. These findings emphasize the broader role of education not only in individual decision-making but also in shaping household-level health-seeking behaviors.

Media exposure was identified as a protective factor against home delivery. Increasing exposure to media can alter perceptions positively and encourage expectant mothers to choose facility-based deliveries over home deliveries, as public awareness and health-related behaviors are strongly influenced by media exposure. Owing to a lack of knowledge, cultural customs, and restricted access to medical facilities, home deliveries continue in many areas. To promote institutional deliveries and enhance the health of mothers and newborns, increasing media exposure can be a useful tactic [42,43]. In Nigeria, similar findings have been reported, where increased usage of maternal healthcare services was linked to media exposure [44]. Expanding media-based health awareness programs could be an effective strategy to reduce home delivery rates further.

366 Religious beliefs also play a role in home delivery choices. Our research suggests that Muslim
367 women exhibited a greater tendency for home delivery than their non-Muslim peers did. Cultural
368 norms, traditional beliefs, and socioeconomic factors may contribute to this trend [45]. A similar
369 pattern has been observed in India, where women of the Muslim faith exhibited a greater propensity
370 for home births [36]. However, further research is necessary to investigate the underlying causes of
371 this difference and to develop culturally relevant treatments that encourage institutional deliveries
372 within various religious communities.

373 The utilization of antenatal care (ANC) is a crucial factor influencing home delivery, as women
374 who visit four or more ANC appointments are much less inclined to deliver at home. This aligns
375 with findings from Afghanistan, where ANC visits were strongly associated with lower home
376 deliveries [46]. High-quality ANC services provide essential counseling, health screenings, and
377 education on the benefits of skilled birth attendance, which collectively influence women's
378 decisions to seek facility-based delivery over home delivery [47–51]. The consistent relationship
379 between ANC utilization and a lower likelihood of home delivery highlights the need to strengthen
380 ANC services and ensure equitable access for all pregnant women.

381 Parity, or the number of previous childbirths, also influenced home delivery rates. Home deliveries
382 were more common among women with three or more children. This finding is similar to those of
383 studies conducted in Bangladesh and Ethiopia, which reported that women who are first-time
384 mothers or have fewer pregnancies are more likely to choose facility-based births [30,37]. Likewise,
385 multiparous women in rural Zambia are more inclined to give birth at home [52]. Women with
386 multiple previous births may feel more confident about delivering at home, particularly if they have
387 had uncomplicated deliveries in the past. Furthermore, multiparous women may be more likely to

388 opt for delivery at home because of logistical difficulties, financial limitations, and a dependence
389 on traditional birth attendants. Addressing these barriers through community-based interventions
390 and financial support programs could help encourage facility-based deliveries among high-parity
391 women.

392 Our findings highlight a strong wealth disparity in home delivery rates. Women from poorer
393 households were significantly more likely to give birth at home than those from affluent households
394 were. Similar findings have been reported in several countries, including Nigeria, Nepal, and India
395 [53–56]. Financial constraints, out-of-pocket fees, and indirect costs such as transportation and lost
396 wages may deter women from seeking facility-based deliveries. Studies from Kenya and West
397 Africa similarly report persistent economic disparities in maternal healthcare utilization,
398 emphasizing the need for financial support mechanisms such as conditional cash transfers and
399 subsidies to promote institutional deliveries among economically disadvantaged groups [47,48,57].

400 Urban–rural differences in home delivery rates were also evident. Home deliveries were more
401 common among women in rural areas. According to some studies conducted in Africa and
402 Indonesia, urban women are significantly more likely than their rural counterparts are to give birth
403 in a medical facility [58–60]. Women living in rural areas confront unique obstacles to facility
404 delivery, such as a lack of qualified healthcare personnel, restricted availability of medical services,
405 and poor healthcare infrastructure [44,49,61,62]. Bridging the urban–rural gap in maternal
406 healthcare requires strategic investments in rural healthcare facilities, improved transportation
407 networks, and community-based healthcare interventions.

408 Bangladesh has implemented a range of interventions over the past decade-including the expansion
409 of community clinics, maternal health voucher schemes, and awareness campaigns-that have

contributed to the overall reduction in maternal delivery at home and increased skilled birth attendance [63]. The Maternal Health Voucher Scheme (MHVS), launched in 2007, has been particularly impactful in improving access to antenatal care, skilled assistance at delivery, and postnatal care among disadvantaged women, though administrative and coverage challenges remain [64,65]. Our study affirms the success of these efforts at the national level but also reveals persistent gaps: maternal delivery at home remains disproportionately high among marginalized groups such as women in the hill tracts, high-parity mothers, and the poorest households. Additionally, our findings highlight that determinants of maternal delivery at home differ between urban and rural settings, with factors like religion and household head's education being more influential in urban areas, while wealth, parity, and ANC visits are more critical in rural regions. These context-specific disparities suggest that, despite overall progress, current interventions have not fully addressed the unique barriers faced by these populations. To further reduce maternal delivery at home, particularly in high-prevalence areas, our study recommends mobile and culturally sensitive outreach in remote districts, greater engagement of religious and community leaders, incentivization of complete ANC utilization, and adaptation of policies to the distinct socio-demographic realities of different regions.

Strengths and Limitations

A key strength of this study is its ability to provide valuable insights at both the national and subnational levels using data from the MICS 2012–13 and 2019, as well as the BDHS 2022. Despite the widespread use of spatial analysis in disease transmission research, few studies in Bangladesh have examined spatial and temporal trends in maternal delivery at home. The use of the most recent

BDHS 2022 dataset, which employed rigorous sampling techniques, enhances the generalizability of the findings to women of reproductive age (15–49 years) across the country. Additionally, the large sample size and application of appropriate statistical techniques allowed for robust identification of significant predictors and assessment of inequality gradients across multiple subgroups. The findings can inform policies aimed at reducing maternal delivery at home clusters and identifying areas with limited access to facility-based childbirth services.

However, the study has certain limitations. First, as with most MICS and DHS-based studies, data are self-reported and thus subject to recall bias and social desirability bias, which may affect the accuracy of reported reproductive behaviors. Second, due to the cross-sectional nature of the survey, the study cannot establish causal relationships between maternal delivery at home and its determinants. Third, some relevant covariates—such as maternal comorbidities, nutritional status, dietary patterns, physical activity, and psychosocial factors—were not included in the BDHS and thus could not be examined, even though they may have significant implications for maternal delivery at home. Finally, socioeconomic characteristics were measured at the time of the interview, which may not accurately reflect the woman's status at the time of pregnancy or childbirth.

Conclusion

Over the last decade, Bangladesh has made great strides in lowering the country's home delivery rates. However, one-third of births still occur at home, highlighting ongoing challenges in ensuring universal access to institutional deliveries. Geographic, socioeconomic, and demographic disparities persist, underscoring the need for targeted interventions. Strengthening healthcare infrastructure, particularly in remote and hilly areas, improving maternal health education, and increasing ANC utilization can further reduce home deliveries. Additionally, addressing financial barriers through subsidies and incentive programs may encourage greater use of facility-based care.

Culturally sensitive approaches, media-based awareness campaigns, and community engagement initiatives should be prioritized to achieve equitable maternal healthcare access. To develop inclusive and successful policies, future studies should look at how religious, cultural, and economic issues affect decisions about maternal delivery at home. Bangladesh may achieve universal facility-based birthing by resolving these inequities, which would ultimately improve the health of expectant mothers and newborns.

Declarations

Acknowledgements: We are grateful to the MICS and DHS team for allowing us to conduct the analysis of this study using the MICS 2012 and 2019 data set and the BDHS 2022 data set.

Author Contributions: Conceptualization, M.L.K, and R.B.I; Data curation, R.B.I, and M.L.K; Formal analysis, R.B.I, and M.L.K; Methodology, R.B.I, and S.T.A.N; Visualization, R.B.I, and S.T.A.N; Investigation, S.M., and A.A; Supervision; Validation, M.B.L; Writing—original draft, R.B.I, S.T.A.N and M.L.K; Writing - review and editing, S.M., A.A., and M.B.L; All authors have read and agreed to the published version of the manuscript.

Funding: The authors received no specific grant from funding agencies in the public, commercial, or not-for-profit sectors.

Consent for publication: Not applicable.

Competing interests: There are no potential conflicts (financial, professional, or personal) for any of the authors to disclose.

Data availability: All data relevant to the study are included in the article or uploaded as supplemental information. All relevant data are within the manuscript. Raw MICS (https://mics.unicef.org/) and BDHS (https://dhsprogram. com/) data are publicly available that can be accessed upon request.
