19 Abstract

20 Background: Mistletoe extracts are used as an adjunct therapy for cancer patients, but there is dissent
21 as to whether this therapy has a positive impact on quality of life (QoL).

22 Methods: We conducted a systematic review searching in several databases (Medline, Embase,
23 CENTRAL, CINAHL, PsycInfo, Science Citation Index, clinicaltrials.gov, opengrey.org) by combining
24 terms that cover the fields of “neoplasm”, “quality of life” and “mistletoe”. We included prospective
25 controlled trials that compared mistletoe extracts with a control in cancer patients and reported QoL
26 or related dimensions. The quality of the studies was assessed with the Cochrane Risk of Bias tool
27 version 2. We conducted a quantitative meta-analysis.

28 Results: We included 26 publications with 30 data sets. The studies were heterogeneous. The pooled
29 standardized mean difference (random effects model) for global QoL after treatment with mistletoe
30 extracts vs. control was $d = 0.61$ (95% CI 0.41-0.81; $p < 0,00001$). The effect was stronger for younger
31 patients, with longer treatment, in studies with lower risk of bias, in randomized and blinded studies.
32 Sensitivity analyses support the validity of the finding. 50% of the QoL subdomains (e.g. pain, nausea)
33 show a significant improvement after mistletoe treatment. Most studies have a high risk of bias or at
34 least raise some concern.

35 Conclusion: Mistletoe extracts produce a significant, medium-sized effect on QoL in cancer. Risk of bias
36 in the analyzed studies is likely due to the specific type of treatment, which is difficult to blind; yet this
37 risk is unlikely to affect the outcome.

42

43

44 Background

45 Mistletoe has been used for centuries as a folk remedy, dating back to ancient Greek and Celtic
46 medicine [1, 2]. Today's use of preparations of the European mistletoe (*Viscum album L.*) in
47 anthroposophic medicine and particularly the treatment of cancer patients has been introduced by
48 Rudolf Steiner (1861-1925) in the 1920s [3] and developed further by Ita Wegmann and various
49 clinicians and pharmacists in this tradition. The basis for this development were, apart from the
50 traditional pharmacopeias, specific anthroposophic investigations involving the phenomenology of
51 mistletoe that grows as a semi-parasite on trees. These and other considerations led Steiner and
52 associates to try mistletoe treatment for cancer. Out of this suggestion a long tradition of empirical
53 knowledge has developed, especially in Germany and Europe. *Viscum album* extract (VAE) is applied
54 subcutaneously, normally two to three times per week whereas the complete treatment duration
55 varies from some weeks up to five years and more. Different products are available such as
56 ABNOBAViscum, Helixor, Iscador, or Lektinol.

57 Mistletoe contains biologically active molecules including lectins, flavonoides, viscotoxins, oligo- and
58 polysaccharides, alkaloids, membrane lipids and other substances [4]. Although the exact
59 pharmacological mode of action of mistletoe is not completely elucidated, there is a growing number
60 of biological studies with a clear focus on lectins. Lectins (from the Latin *legere*, "to select") are
61 carbohydrate-binding proteins displayed on cell-surfaces to convey the interaction of cells with their
62 environment [5]. Lectins mediate many immunological activities: For example, lectins show an
63 immunomodulatory effect on neutrophils and macrophages by increasing the natural killer cytotoxicity
64 and the number of activated lymphocytes [6-8]. They induce apoptosis in human lymphocytes [9] and
65 boost the antioxidant system in mice [10]. In healthy subjects, the subcutaneous application of
66 mistletoe has stimulated the production of granulocyte-macrophage colony-stimulating factor (GM-
67 CSF), Interleukin 5 and Interferon gamma [11], indicating the immunopotentiating properties of
68 mistletoe. The multiple ways how mistletoe affects the immune system have been recently reviewed
69 elsewhere [12]. In consequence, the immunological pathways of conventional oncological treatments

70 may be influenced by VAE, affecting cancer cells and decreasing adverse effects. This may result in a
71 better quality of life (QoL).

72 A number of reviews has been published over the last two decades that address the effects of VAE on
73 QoL in cancer patients [13-19]. However, these studies are either out of date, don't make use of all
74 published evidence, and/or don't combine the data quantitatively into a pooled effect size.

75 The aim of this study is therefore to review and analyze the current evidence regarding QoL of cancer
76 patients which were treated with VAE and to calculate a meta-analysis.

77

78

79 **Methods**

80 The study has been reported in accordance to PRISMA. The protocol was submitted to PROSPERO
81 (registration number: CRD42019137704).

82 **Sources of evidence**

83 We searched the databases Medline, Embase, PsychInfo, CENTRAL, CINAHL, Web of Science, and
84 clinicaltrials.gov, we used google scholar, hand-searched the reference lists of reviews and identified
85 studies and screened for grey literature via Google and opengrey.org. In case of missing data we
86 contacted the authors.

87

88 **Search strategy**

89 We developed a search strategy by iteratively combining synonyms and/or subterms of "quality of life"
90 (e.g. well-being, QoL), "cancer" (e.g. neoplasm, sarcom, lymphom) and "mistletoe" (e.g. Helixor,
91 Eurixor) to identify an adequate set of terms. We applied the following search strategy for Medline
92 (Pubmed) and adopted it to the other databases accordingly:

- 93 1. quality of life OR HRQoL OR HRQL OR QOL OR patient satisfaction OR well-being OR wellbeing
- 94 2. mistel OR mistletoe OR Iscador OR Iscar OR Helixor OR Iscucin OR Abnobaviscum OR Eurixor
- 95 OR Plenosol OR Lektinol OR Vysorel OR Isorel OR Cefalektin OR Viscum

- 96 3. Krebs OR cancer OR neoplasm/ OR tumor OR oncolog* OR onkologie OR carcin* OR malignant
97 OR metastasis
98 4. Humans[MESH]
99 5. 1 AND 2 AND 3 AND 4

100 With the exception of #4 the general search fields were applied.

101

102 **Selection criteria**

103 We included studies that measured QoL or self-regulation of cancer patients treated with mistletoe
104 extracts assessed by performance status scales or patient-reported instruments. Studies were chosen
105 if they were

- 106 • prospective controlled studies with
- 107 • two or more arms,
- 108 • both interventional and non-interventional.

109 The search was not limited to languages.

110 Studies were excluded if

- 111 • they did not meet the aforementioned inclusion criteria,
- 112 • if they tested multi-component complementary medicine interventions,
- 113 • if they failed to report sufficient information to be included into the meta-analysis or
- 114 • where this information cannot be gleaned from authors or extracted from graphs.

115 **Data management**

116 The data was extracted from each study and entered into a spreadsheet by two authors independently.

117 Then the extracted spreadsheets were compared and discrepancies were resolved by discussion until
118 consensus was reached. We coded the following characteristics:

- 119 • number of participants in each treatment arm
- 120 • year, when study was conducted; in case this was not given, we estimated a 3 year lag from
121 publication date for the meta-regression

- 122 • duration of study
- 123 • country where the study was conducted
- 124 • cancer type
- 125 • age
- 126 • gender of patients
- 127 • diagnosis according to ICD 10
- 128 • duration of study
- 129 • type of study (interventional vs. non-interventional, randomized vs. non-randomized, blinded
- 130 vs. not blinded, single vs. multi-center)
- 131 • additional therapy (e.g. chemotherapy)
- 132 • number of drop-outs in each study arm
- 133 • active mistletoe extract preparation (e.g. Eurixor, Iscador, etc.)
- 134 • control treatment (e.g. placebo)
- 135 • effect size of primary outcomes plus standard deviation, or confidence intervals for effect
- 136 measure provided using the reported global measure of QoL
- 137 • instrument used to measure primary outcomes
- 138 • statistics according to intent-to-treat analysis (yes/no)
- 139 • sponsoring of study (corporate, public, no-sponsoring).

140

141 If numerical data provided by the study publication was insufficient to calculate effect sizes, we

142 contacted the authors. In cases where additional data were provided by the authors, these were then

143 used instead of the published data. In older studies this was impossible. In those cases we used the

144 given information (for instance means and confidence intervals, or means and p-values, or statistical

145 information to generate the necessary data). In some cases we had to use medians as means and

146 recover standard errors of the means from the given confidence intervals which also necessitated an

147 adaptation of the confidence intervals into symmetrical ones. In each case we used the more

148 conservative option which yielded larger standard errors and hence larger standard deviations. Thus,
149 we generally opted for an error on the conservative side. When no quantitative information was given,
150 but only graphs were presented, we printed high resolution graphs and derived the mean values and
151 standard errors applying a ruler and used the given statistical information to arrive at the necessary
152 quantitative scores. All these procedures were conducted independently and in duplicate [20].

153

154 **Risk of bias (quality) assessment**

155 The Cochrane Risk of Bias tool 2 (Rob 2) was used to assess the risk of bias in randomized controlled
156 trials [21]. All studies were assigned to the intention-to-treat-effect-analysis. Non-randomized or non-
157 interventional studies were additionally analyzed with the Newcastle Ottawa Scale [22]. Two reviewers
158 (HW, ML) independently assessed the risk of bias. In case of discrepancies they decided by consensus.

159

160 **Statistical analysis**

161 The data were analyzed using Comprehensive Meta-Analysis V. 2 and Revman 5.3.5, the summary
162 measure was the standardized mean difference. The meta-analysis was calculated independently by
163 both authors using the two software tools Comprehensive Meta-Analysis and RevMan. The results
164 were compared and underlying discrepancies resolved by discussion until both analyses yielded the
165 same numerical results up to the second decimal. We report the overall analysis according to the
166 results yielded by the RevMan analysis and conducted sensitivity analyses with Comprehensive Meta-
167 Analysis.

168

169 The heterogeneity between studies was assessed by the Cochrane Q test and quantified by the index
170 of heterogeneity (I^2) [23]. A value of I^2 of 25%, 50% and 75% indicates low, medium and high
171 heterogeneity, respectively. If heterogeneity was higher than 25% we applied a random effects model
172 for pooling the data, else a fixed effects model was used. As heterogeneity was high for the overall

173 data-set, a random effects model was indicated. Fixed effect models were only used sparingly in
174 exploratory subgroup analyses or sensitivity analyses, when heterogeneity was low.

175
176 We conducted subgroup analysis in order to identify possible sources of the heterogeneity. Stratified
177 analyses were performed by: study types (e.g. blinded vs. not blinded, randomized versus non-
178 randomized, types of control), additional treatments, country, risk-of-bias status, type of sponsoring,
179 QoL instruments and related dimensions (in particular self-regulation), and mistletoe compound. Type
180 of cancer was not included, as there were too many different cancer types. We conducted meta-
181 regressions and regressed the three continuous predictors year of study, age of patients and length of
182 treatment on effect size. We checked for publication bias using Egger's regression intercept method
183 and Duval and Tweedie's trim and fill method [24].

184

185 Results

186 598 studies were identified by electronic and hand searches, after removing duplicates. 67 full texts
187 were retrieved of which 26 publications with 30 separate data sets met the inclusion criteria (see figure
188 1) [25-50]. We contacted 14 authors for additional information which was granted by five [25, 29, 39,
189 49, 51].

190

191 Insert here: fig. 1

192

193 90% of the studies were conducted in Europe including Russia, 50% in Germany, and 10% in Asia. Three
194 trials were blinded, four studies or datasets were not randomized. Different mistletoe preparations
195 with varying conventional treatments were compared to conventional treatment (alone in 22 cases or
196 plus an additional comparator in eight cases, respectively) for multiple types and stages of cancer. In
197 nine studies QoL was measured with EORTC-QLQ-C30, six studies assessed self-regulation, and the
198 others used one or multiple other instruments. The study characteristics are displayed in table 1.

Insert here: tab. 1

The results of the overall meta-analysis are presented in Figure 2.

Insert here: Figure 2.

As can be seen the studies are highly heterogeneous ($I^2 = 84\%$), and hence the random effects model is applied to estimate the combined standardized mean difference as $d = 0.61$ (95% CI 0.41-0.81, $p < 0.00001$, $z = 6.05$).

The meta-analyses of the sub-dimensions of QoL are shown in table 2. The SMD of seven out of 14 QoL dimensions are significant ($p \leq 0.05$). The pooled SMD of role and social functioning are 0.63 (95% CI 0.05-1.22) and 0.62 (95% CI 0.22-1.03), respectively. For pain, it is $SMD = -0.86$ (95% CI -1.54-(-0.18)) and for nausea, it is $SMD = -0.55$ (95% CI -1-(-0.1)).

Insert here: tab. 2

The risk of bias assessment is displayed in the figures 3 and 4. 65% had an overall high risk of bias which resulted for most studies from the 85% high risk of bias in the measurement of outcome. This can be attributed to the missing blinding process, the QoL assessment as patient-reported outcome, and the uncertain appropriateness of some measurement instruments which may only incompletely capture the concept of QoL.

Insert here: fig. 3

225

226 The five non-randomized trials [30, 33-35, 42] were additionally assessed with the Newcastle-Ottawa-
227 scale. All studies had an overall score of 7 out of a maximum of 9. The sums in the selection, the
228 comparability and the outcome/exposure domain were 3, 2 and 2, respectively, for all studies.

229

230

231 Insert here: fig. 4

232

233 The sensitivity analyses are presented in Table 3.

234

235 Insert here: tab. 3

236

237 The sensitivity analyses confirmed the robustness of the results. Neither the methodological nor other
238 moderator variables showed strong deviations. With the exception of the non-randomized studies
239 (non-randomized: $d = 0.38$, $p = 0.1$), the lung cancer studies ($d = -0.18$, $p = 0.15$), the studies conducted
240 with Lektinol ($d = 0.67$, $p = 0.1$), and the studies using an index measure (e.g. Karnofsky index) as
241 outcome ($d = 0.33$, $p = 0.1$) all other moderator analyses showed no appreciable differences between
242 subgroups and yielded highly significant effect sizes. In tendency, methodologically more rigorous
243 studies yielded higher or equally high effect sizes than less rigorous ones. Most notably, randomized
244 studies yielded a higher effect size ($d = 0.70$, $p = 0.001$) than non-randomized ones ($d = 0.38$, $p = 0.1$).
245 Studies using active controls ($d = 0.6$, $p = 0.004$) did not differ from studies using other controls ($d =$
246 0.65 , $p < 0.001$). Various types of additional treatment did not show differential effect sizes, except
247 individualized best care, which, however, is an estimate based on only one study and hence not
248 reliable. Although the effect sizes of the various products vary, their confidence intervals overlap, and
249 hence suggest the conclusion that they are roughly equally effective. There is no difference in effect
250 sizes depending on countries, type of sponsoring, or type of measures. Studies that relied on corporate

251 sponsoring, and studies using only a single index measure yielded a somewhat smaller effect size,
252 although confidence intervals overlap and thus signal non-significant differences.

253

254

255 The three meta-regressions are presented in Table 4 and in Figures 5 and 6.

256

257 Insert here: tab. 4

258

259 Insert here: fig. 5

260

261

262 The study year is positively correlated with effect size. For each year the study was more recent the
263 estimated QoL-effect size is larger by $d = 0.03$. Although there is a tendency for a larger effect size in
264 younger patients this effect is not significant. The slope of the regression line for the duration of
265 treatment is borderline significant, indicating that longer treatment produces effects that are 0.04
266 standard deviations larger per additional treatment week. Note though that only treatments between
267 5 and 52 weeks have entered the analysis and the variance is not large.

268

269 Insert here: fig. 6

270

271 Publication bias was estimated using two methods. Egger's regression intercept model regresses effect
272 size on precision of study with the assumption that smaller studies that are less precise will more often
273 go unpublished. A regression line with a lot of smaller and more imprecise studies missing should thus
274 miss the origin by a large margin. In our analysis the intercept of the regression is 0.82 with a non-
275 significant deviation from the origin ($t = 0.65$, p -value two tailed = 0.5). Duval and Tweedie's trim and
276 fill method is an extension of the graphical funnel plot analysis and analyzes how many studies would

277 have to be trimmed to generate a perfectly symmetrical funnel plot. In our analysis this method
278 estimates no studies to be trimmed on the left side, i.e on the negative or low side of the effect size
279 estimate and an estimate of 7 trimmed studies on the right side, i.e. on the positive side of the effect
280 size funnel with an adjustment that leads to a higher effect size, if the studies are trimmed. These two
281 analyses of publication bias show that publication bias is not a likely explanation of this result and any
282 funnel asymmetries are not due to unpublished studies but due to positive outliers.

283

284

285 Discussion

286 This meta-analysis shows a significant and robust medium-sized effect of $d = 0.61$ of viscum album
287 extract (VAE) treatment on QoL in cancer patients.

288 The results should be regarded in the light of the following facts:

289 The included studies vary with regard to the cancer site, the control intervention, the additional
290 oncological treatment, and the VAE. While sensitivity analyses confirmed the robustness and reliability
291 of the findings, they could not account for the heterogeneity of the effect sizes. Neither
292 methodological moderators (blinded vs. unblinded studies, randomized versus non-randomized,
293 studies with high versus low risk of bias, active versus non-active control) nor structural moderators
294 (type of outcome measure, funding, VAE product used, additional treatment) could clarify the
295 heterogeneity. We suspect that this is due to multiple interactions between cancer types and stages,
296 treatments and structural variables that cannot be explored with a limited set of 30 studies.
297 Nevertheless, our sensitivity analyses document the overall robustness of the effect, as none of the
298 levels of moderators exhibits significant deviations from other levels or from the overall effect size.
299 This gives our effect size estimate of $d = 0.61$ reliability.

300 Although the overall risk of bias is high in many studies, one should bear in mind two aspects. First, we
301 applied the intention-to-treat-algorithm of Rob2 as the more conservative approach and not the per-
302 protocol evaluation which may have resulted in a better overall bias. Second, due to the local skin

303 reaction of VAE application the blinding of participants and carers is practically impossible and could
304 only have been implemented reliably with an active placebo, which is ethically questionable. In Rob2
305 this leads to a high risk of bias in the measurement of the outcome. On the one hand, the lack of
306 blinding might have biased the results since most QoL are self-reported and there may be strong beliefs
307 among users of anthroposophic medicine which might additionally be fortified by the severity of the
308 disease and the hope that an additional treatment has a positive impact [52]. It was shown that these
309 attitudes are correlated with a better QoL [53]. On the other hand, there is no evidence from the
310 included studies that the attitudes differed between treatment arms and if patients in the control
311 group searched and used for surrogate medications for the VAE, this bias would favor the comparator.
312 Furthermore, our sensitivity analysis gives no indication that studies with blinding and without blinding
313 estimate different effect sizes and there is also no difference in effect sizes between studies from
314 Germany – where mistletoe is well known – and other countries where mistletoe is less known and
315 used. The results of the Newcastle-Ottawa-Scale, finally, indicate a good methodological quality for
316 the non-randomized trials that were included in the review.

317
318 Another limitation is that self-regulation, the Karnofsky performance index, or the ECOG scale cover
319 important aspects of QoL, but are different in content from other measures such as the global QoL of
320 the EORTC-QLQ C30 scale. This source of heterogeneity was also addressed by our sensitivity analyses.
321 This showed that, indeed, as one would expect, single item indices estimate lower effect sizes,
322 although the difference is not significant. In the same vein, the inclusion of non-randomized and non-
323 interventional trials might have biased the results due to their lower internal validity, but their
324 exclusion during sensitivity analyses again did not alter the significance of the pooled outcome. In
325 addition, four of the five non-RCTs had a matched-pair design which increases the comparability
326 between treatment arms compared to other types of group allocation.

327 The meta-regression shows that more recent studies have higher effect sizes compared to older
328 studies. This is counterintuitive at first sight, as normally more recent studies are implemented with

329 more methodological rigor due to the GCP guidelines and a higher methodological skill of trialists. This,
330 one would think, should, if at all, lead to smaller effect sizes in more recent trials. The fact that this is
331 not the case shows, together with our sensitivity analysis that methodological bias is an unlikely
332 explanation for the effect size found. However, another point is worth bearing in mind: earlier studies
333 were very often implemented with severely ill patients with tumor status IV or in palliative care. Only
334 in more recent studies was VAE also used as add on treatment in first line patients with a relatively
335 good chance of surviving. Thus the higher effect size for more recent studies might also reflect the less
336 severe status of these patients.

337

338 Our review has a number of strengths. First, we conducted a comprehensive search for published and
339 grey literature with no time or language limitation to minimize publication bias. Our analysis of
340 publication bias supports the conclusion that the effect size estimate is not due to publication bias.
341 Some authors who we contacted, however, failed to provide additional information and the respective
342 studies were consequently excluded. Second, we calculated a pooled SMD for a global measure of QoL
343 and for its subdomains such as pain or fatigue. Third, we analyzed the data both with Revman 5.3 and
344 CMA software which implements the Hunter-Schmidt-corrections for small sample bias. We did both
345 analyses in parallel and independently, thus preventing coding or typing errors from biasing our results.

346

347 The weaknesses of this review are obvious. Any meta-analysis can only be as good as the original
348 studies entered. Some of these studies are large and methodologically strong. But some are also badly
349 reported, small and with a mixed patient load. In some cases we had to recalibrate confidence interval
350 estimates, because the data given were not detailed enough. Although it would have been desirable,
351 the variance between cancer types and stages was too large to allow for detailed assessments and
352 separate analyses, which might have reduced the heterogeneity. Although we can testify to the
353 robustness of the overall effect size estimate, we have not succeeded in clarifying the heterogeneity
354 of the studies. This requires multi-center studies in large cohorts of patients with large budgets. Thus,

355 one consequence of this meta-analysis would be to call for more serious efforts from public funders to
356 study the effects of VAEs in large and homogeneous patient cohorts to confirm or disconfirm the
357 results of this analysis.

358

359 Clinical relevance

360 Our results indicate a statistically significant and clinically valuable improvement of the subjective well-
361 being of patients with different types of cancer after the treatment with VAE. The analyses for the
362 subdomains revealed a significant pooled SMD for important symptoms and functioning indices,
363 whereas other show a positive, yet not significant effect of VAE compared to control. Whether these
364 vital elements of QoL such as emotional functioning or fatigue are influenced remain statistically
365 uncertain. Overall, a robust estimate of an improvement of $d = 0.61$ in quality of life represents a
366 medium-sized [54] and clinically relevant [55, 56] effect that makes VAE treatment a viable add-on
367 option to any anticancer treatment.

368

369 Conclusion

370 Our analysis provides evidence that global QoL in cancer patients is positively influenced by VAE.
371 Because the risk of bias and the heterogeneity is high, future research needs to better assess the actual
372 impact. Large studies in homogeneous patient populations are required to address these problems.

380 Availability of Data and Materials

381 The database on which this study is based is available on request from the authors.

382 Competing Interests

383 The authors have no conflict of interest to declare.

384 Funding

385 This study was funded by the Förderverein komplementärmedizinische Forschung, Arlesheim,

386 Switzerland.

387 Authors' Contributions

388 Both authors contributed equally. HW developed the protocol, ML edited and improved it and

389 submitted it to PROSPERO. ML developed and implemented the search strategy. Both authors

390 extracted the data independently, discussed discrepancies, and calculated the analyses

391 independently. ML calculated the quantitative analysis reported and HW calculated the sensitivity

392 analyses reported. ML wrote the first draft of the paper and HW edited and contributed to writing.

393 Both authors analyzed and interpreted the data. All authors have read and approved the manuscript.

Tab. 1

Reference	Country	Study type	Participants (number at baseline; number of females; mean age)		Cancer, stage	Intervention		QoL measurement
			verum	control		verum	control	
Bar-Sela 2013	Israel	single-center, randomized, 2 arms, unblinded, interventional	33; 5; 63	39; 11; 62	lung cancer (NSCLC), IIIa, IIIb, IV	chemotherapy, Iscador Q	chemotherapy	EORTC-QLQ-C30
Borrelli 2001	Italy*	randomized, 2 arms, unblinded, interventional	20; 20; n/a	10; 10; n/a	breast cancer, IV	surgery/ chemotherapy, then mistletoe extract	surgery/ chemotherapy, then water	Spitzer QoL
Dold 1991	Germany	multi-center, randomized, 2 arms, unblinded, interventional	114; 6; 65,6	113; 6; 67,5	lung cancer (NSCLC), I-IV	conventional oncological therapy, Iscador Q	conventional oncological therapy, BVK Roche	KPI
Enesel 2005	Romania*	randomized, 2 arms, unblinded, interventional	40; n/a; n/a	30; n/a; n/a	digestive tract cancer, n/a	surgery, Isorel A	surgery	KPI
Grah 2010	Germany	single-center, randomized, 2 arms, unblinded, interventional	26; 7; 64,3	24; 7; 63	lung cancer (NSCLC), IIIb, IV	chemotherapy, Iscador Q spezial	chemotherapy	EORTC-QLQ-C30

Grossarth-Maticek, 2006a	Germany	multi-center, multiple data-sets, randomized/ not randomized, 2 arms, unblinded, interventional/not interventional, nested matched pairs	MammaRand: 39; 39; 52,8 Mamma: 97; 97; 52,2	MammaRand: 39; 39; 52,9 Mamma: 97; 97; 52,2	breast cancer, T1a-T3	conventional oncological therapy, Iscador	conventional oncological therapy	self-regulation
Grossarth-Maticek, 2006b	Germany	multi-center, randomized, 2 arms, unblinded, interventional, nested matched pairs	17; 17; 44,5	17; 17; 44,6	breast cancer, T2-4	conventional oncological therapy, Iscador	conventional oncological therapy	self-regulation
Grossarth-Maticek, 2007a	Germany	multi-center, multiple data-sets, randomized/ not randomized, 2 arms, unblinded, interventional/not interventional, nested matched pairs	Cervix: 102; 102; 51 CervixMetRand: 19; 19; 47,7	Cervix: 102; 102; 51 CervixMetRand: 19; 19; 47,6	cervical cancer, IB-IVa	conventional oncological therapy, Iscador	conventional oncological therapy	self-regulation
Grossarth-Maticek, 2007b	Germany	multi-center, multiple data-sets, randomized/ not randomized, 2 arms, unblinded, interventional/not interventional, nested matched pairs	Ovar: 75; 75; 43 OvarRand: 21; 21; 45,4	Ovar: 75; 75; 45,1 OvarRand: 21; 21; 45,5	ovarian cancer, IA-C, IV	conventional oncological therapy, Iscador	conventional oncological therapy	self-regulation
Grossarth-Maticek, 2007c	Germany	multi-center, randomized, 2 arms, unblinded, interventional, nested matched pairs	22; 8; 52	22; 8; 52	melanoma, n/a	conventional oncological therapy, Iscador	conventional oncological therapy	self-regulation

Grossarth-Maticek, 2008	Germany	multi-center, multiple data-sets, randomized/ not randomized, 2 arms, unblinded, interventional/not interventional, nested matched pairs	Corpus: 105; 105; 58,5 CorpusRand: 31; 31; 55,1	Corpus: 105; 105; 59,1 CorpusRand: 31; 31; 55,1	corpus uteri cancer, IA-C, IIIa-IVb	conventional oncological therapy, Iscador	conventional oncological therapy	self-regulation
Heiny 1991	Germany*	randomized, 2 arms, unblinded, interventional	25; 25; n/a	21; 21; n/a	breast cancer, advanced	chemotherapy, Eurixor	chemotherapy, infusion of saline solution	QoL scale based on FLIC, self-assessment
Heiny 1997/1998	Germany*	randomized, 2 arms, unblinded, interventional	38; 16; 54,7	41; 18; 53,2	colorectal cancer, advanced	chemotherapy, Eurixor	chemotherapy	FACT-G
Kaiser 2001	Germany*	randomized, 2 arms, blinded, interventional, cross-over	29; 15; n/a in both arms	29; 15; n/a in both arms	multiple cancer, n/a	n/a, AbnobaVISCUM Mali 4	n/a, isotone puffer	ECOG
Kim 2012	South Korea	single-center, randomized, 2 arms, unblinded, interventional	16; 3; 53,8	16; 3; 54,9	gastric cancer, Ib, II	waiting for chemotherapy, AbnobaVISCUM Q	waiting for chemotherapy	EORTC-QLQ-C30
Lange 1988	Germany	single-center, randomized, 2 arms, unblinded, interventional	35; 9; 58,3	33; 9; 60,2	multiple cancer, n/a	conventional oncological therapy, Helixor A	conventional oncological therapy	KPI
Lenartz 1996	Germany*	randomized, 2 arms, unblinded, interventional	18; 6; 52	17; 7; 52	glioma, III-IV	conventional oncological therapy, mistletoe extract	conventional oncological therapy	Spitzer QoL

Loewe-Mesch 2008	Germany	single-center, not randomized, 2 arms, unblinded, interventional	39; 39; 47,5	43; 43; 47,5	breast cancer, T1a-c, TII	chemotherapy, Iscador M spezial	chemotherapy	EORTC-QLQ-C30
Longhi 2014	Italy	single-center, randomized, 2 arms, unblinded, interventional	9; 5; 28	11; 4; 39	osteosarcoma, IB- IIIB	Iscador P	Etoposide (oral)	EORTC-QLQ-C30
Piao 2004	China	multi-center, randomized, 2 arms, unblinded, interventional	118; 91; 52,6	115; 91; 51,7	multiple cancer, pTx, pT1-4	chemotherapy, Helixor	chemotherapy, Lentinan (i.m.)	TCM, FLIC, KPI
Semiglasov 2004	Bulgaria, Russia, Ukraine	multi-center, randomized, 4 arms, blinded, interventional	67; 67; 44,6	70; 70; 43,5	breast cancer, pT1-3	chemotherapy, Lektinol (PS76A)	chemotherapy, placebo	GLQ-8, Spitzer uniscale
Semiglasov 2006	Bulgaria, Russia, Ukraine	multi-center, randomized, 2 arms, blinded, interventional	176; 176; 46,4	176; 176; 45,9	breast cancer, pTis-pT3	chemotherapy, Lektinol (PS76A)	chemotherapy, placebo	FACT-G, GLQ-8, Spitzer uniscale
Steuer-Vogt 2006	Germany	multi-center, randomized, 2 arms, unblinded, interventional	200; 17; 55	199; 14; 55	head neck cancer, I-IV	surgery, Eurixor	surgery	EORTC-QLQ-C30
Tröger 2009	Serbia	single-center, randomized, 2 arms, unblinded, interventional	30; 30; 48,4	31; 31; 50,8	breast cancer, Tx, T1-3	chemotherapy, Iscador M spezial	chemotherapy	EORTC-QLQ-C30
Tröger 2014a	Serbia	single-center, randomized, 2 arms, unblinded, interventional	34; 34; 50,4	31; 31; 50,8	breast cancer, Tx, T1-3	chemotherapy, Helixor	chemotherapy	EORTC-QLQ-C30
Tröger 2014b	Serbia	single-center, randomized, 2 arms, unblinded, interventional	110; 45; 62,2	110; 47; 64,4	pancreatic cancer, T3-T4	supportive care, Iscador Q	supportive care	EORTC-QLQ-C30
