25 **Abstract**

26 **Background:** Nutrition transition in many low- and middle-  
27 income countries (LMICs) has led to childhood nutritional  
28 outcomes to shift from a predominance of undernutrition to a dual  
29 burden of under- and overnutrition. Yet, Infant and young child  
30 feeding programs in Ethiopia mainly focus on undernutrition. It is  
31 therefore crucial to assess the prevalence and determinants to  
32 better inform infant young child feeding programs.

33 **Methods:** We analyzed anthropometric, sociodemographic and  
34 dietary data of children aged 6-23 months from 2016 Ethiopian  
35 Demographic and Health Survey (EDHS). A total of 2,674  
36 children were included in the current study. Concurrent of Stunting  
37 and Overweight/Obesity (CSO) prevalence was estimated by  
38 distal, intermediate and proximal factors. To identify factors  
39 associated with CSO, we conducted hierarchical logistic regression  
40 analyses.

41 **Results:** The overall prevalence of CSO was 2.45%. The odds of  
42 CSO was significantly higher in children of low household wealth  
43 category, compared to their counter parts in the richest category  
44 (AOR=2.07, 95%CI=1.06–4.03, P=0.033). In boys, the likelihood

45 of CSO was 1.60 times that of girls (95% CI = 1.03–2.49, P  
46 = 0.038). Above 12 months of age was significantly associated with  
47 a higher odd of CSO, compared to below 12 months of age  
48 (AOR = 1.76, 95% CI = 1.07–2.88, P = 0.026).

49 Small birth size was significantly associated with a higher odd of  
50 CSO, compared to large birth size (AOR = 2.53, 95% CI = 1.45–4.41,  
51 P = 0.001). Children who did not take vitamin A supplement within  
52 the previous six months had a higher odd of CSO, compared to  
53 those who took (AOR = 1.91, 95% CI = 1.19–3.07, P = 0.007).

54 **Conclusion:** Our study provided evidence on the co-existence of  
55 stunting and overweight/obesity among infants and young children  
56 in Ethiopia. CSO was associated with various factors originating  
57 from community and child levels. Therefore, identifying children  
58 at risk of growth faltering and excess weight gain provides IYCF  
59 programs in Ethiopia and beyond with an opportunity of earlier  
60 interventions.

67

68 **Introduction**

69 Child malnutrition which includes both undernutrition and  
70 overweight are global challenges which is associated with an  
71 increased risk of mortality and morbidity, unhealthy development,  
72 and loss of productivity[1]. Although improvement of child  
73 undernutrition in Ethiopia has been achieved, stunting remains an  
74 important problem in Ethiopia, with thirty eight percent of children  
75 <5 years of age affected. However, economic growth and  
76 urbanization in countries like Ethiopia have given rise to a  
77 nutrition transition, where there is as shift from traditional diets to  
78 “western diets” (energy-dense diets)[2]. This has led to an increase  
79 in overweight and obesity. On the other hand, undernutrition  
80 decreased but the decline has not been happening as quickly as the  
81 rise in overweight and obesity, leading to a double burden of  
82 overnutrition and undernutrition[3].

83 Dual burden of malnutrition could occur at country, household, or  
84 individual levels. At household level at least one member is  
85 undernourished and at least one member is overweight whereas at  
86 individual level the dual burden of malnutrition often manifests as  
87 stunting or micronutrient deficiencies co-occurring with  
88 overweight or obesity[3-5]. At individual level, history of stunting  
89 coupled with consumption of high dense energy foods and  
90 micronutrient deficiencies owing to shared underlying

91 determinants or physiologic links may also result in clustering of  
92 nutrition problems such as co-occurrence of stunting and  
93 overweight particularly among young children[3].

94 Children who are stunted and gain abnormal weight later can be at  
95 greater risk of unhealthy development than other children. In other  
96 words they are at high risk of non-communicable disease since  
97 they impose a high metabolic load on a depleted capacity for  
98 homeostasis[6]. Further, concurrent under and over nutrition is a  
99 public health challenge in a sense there is a need to strike a  
100 delicate balance between reducing undernutrition and preventing  
101 over nutrition [5]. There are substantial studies on dual burden of  
102 malnutrition and mainly focused on prevalence and trends of  
103 double burden at different levels[2-5, 7-28] but few studies  
104 investigated factors associated with the dual burden at individual  
105 level and in particular among infant and young children [13, 18,  
106 21, 22, 25].

107 To the best of our knowledge there were no previous studies in  
108 Ethiopia on cooccurrence of stunting and overweight among  
109 infants and young children that explored factors associated with it.

110 The previous studies focused on inclusive measure of child  
111 undernutrition and failed to capture the severity of malnutrition for  
112 some children who suffer from more than one type of malnutrition.  
113 Therefore, aim of this study is to assess the prevalence of co-

114 occurrence of stunting and overweight/obese among infants and  
115 young children in Ethiopia and factors associated with it.

116

## 117 **Study subjects and Methods**

### 118 **Study subjects**

119 We analyzed anthropometric data of children aged 6-23 months  
120 from 2016 EDHS which is nationally representative survey. A total  
121 of 2925 children aged 6–23 months were found in the dataset. A  
122 total of 2674 children were extracted and included in the final  
123 dataset after exclusion of incomplete data.

124 A multistage stratified two- stage cluster sampling procedure was  
125 used to select samples. A detailed information of sample design  
126 and procedure is presented elsewhere [29]. We included children  
127 aged 6-23 months with complete height, weight, dietary and non-  
128 dietary data.

### 129 **Study design and data source**

130 We used data set from national representative cross-sectional  
131 household survey that was conducted from September to  
132 December 2015. At individual level, we estimated the prevalence  
133 of double burden of malnutrition defined as co-existence of  
134 stunting and overweight/obese within the same child. Stunting was

135 defined as length-for-age Z-score (LAZ) below -2SD and  
136 overweight/overweight was defined as BMI-for-age Z-score (BAZ)  
137 above 2SD from the respective WHO 2006 growth standards  
138 reference median. Weight were measured using SECA scales while  
139 length was measured using Shorr measuring boards and children  
140 were measured while lying down [29].

141 The data used for this study was extracted from the fourth EDHS.  
142 The survey was implemented by Central Statistical Agency (CSA)  
143 at the request of Ethiopian Federal Ministry of Health (FMoH) and  
144 funded by United States Agency for International Development  
145 (USAID).

#### 146 **Data analysis**

147 Children recode data file in the form of STATA was used for  
148 analysis. Statistical analysis was performed using the STATA  
149 software package, version 14.1 (Stata Corp., College Station, TX,  
150 USA). Survey command (svy) was used to adjust for the complex  
151 sample design.

152 We estimated weighted prevalence of CSO by distal, intermediate  
153 and proximal factors. Overall differences across the categories  
154 were statistically tested using design-based Pearson chi-squared  
155 test. Multiple hierarchical logistic regression was used to examine  
156 the effect of distal, intermediate and proximal factors. First

157 bivariate analyses were done for all potential predictors of CSO.  
158 Then, hierarchical regression models were run using variables  
159 which demonstrated  $P < 0.20$  during the bivariate analyses. The  
160 three-level hierarchical regression models were run following the  
161 recommendation of a previous study that suggested to take into  
162 account complex hierarchical relationships of different  
163 determinants at different level [30]. The first, second, and third  
164 models included distal, intermediate, and proximal factors,  
165 respectively. As mentioned before, variables with  $P < 0.20$  value  
166 during the bivariate analyses were included in the multiple  
167 hierarchical logistic regression analyses. In other words, model-1,  
168 2 and 3 included the distal, intermediate and proximal factors  
169 which demonstrated  $P < 0.20$  during the bivariate analyses. To put it  
170 differently, we used model-1 to assess the overall effect of distal  
171 factors and excluded the intermediate and proximal factors. We  
172 used model 2 to assess the effect of intermediate factors in the  
173 presence of distal factors which were considered confounding  
174 factors. Proximal factors were entered in model 3 in the presence  
175 of distal and intermediate factors which were also considered  
176 confounding variables in model 3. Variable significant at p-value  
177 of 0.05 during the hierarchical regression analyses was considered  
178 to be determinant factor at each model in which the variable was  
179 first entered regardless of its performance in the subsequent

180 model(s). The approach was meant to avoid the possibility of  
181 underestimating the effects of distal factors[30].

## 182 **Result**

### 183 **Background characteristics**

184 The background characteristics of children are presented in Table  
185 1. Fifty three percent of children were females and the rest were  
186 male. Sixty six percent of children were older than twelve□months  
187 and the rest were younger than twelve months. Overall, 31.4 and  
188 11.9% of children were stunted and overweight, respectively. The  
189 overall prevalence of CSO was 2.45%. CSO prevalence among  
190 urban and rural children was 1.62 and 2.56%, respectively. Among  
191 boys and girls, the prevalence was 2.96 and 2.0%, respectively.  
192 The age-specific estimates were 1.86 and 2.77% in those aged  
193 under 12 months and above 12 months, respectively. The  
194 prevalence of CSO by other child characteristics is shown in Table  
195 1.

208

## 209 **Determinants of CSO**

210 The multiple hierarchical logistic regression model presented in  
 211 Table 2 indicated that house hold wealth, child's age and sex, birth  
 212 size and vitamin A supplementation were significantly associated  
 213 CSO.

214 The odds of CSO was significantly higher in children of low  
 215 household wealth category, compared to their counter parts in the  
 216 richest category (AOR=2.07, 95%CI=1.06–4.03, P=0.033). In  
 217 boys, the likelihood of CSO was 1.60 times that of girls (95%CI  
 218 =1.03–2.49, P =0.038). Above 12months of age was significantly  
 219 associated with a higher odd of CSO, compared to below  
 220 12months of age (AOR=1.76, 95% CI=1.07– 2.88, P=0.026).

221 Small birth size was significantly associated with a higher odd of CSO, compared to large birth size (AOR=2.53, 95% CI=1.45–4.41,  
 222 P=0.001). Children who did not take vitamin A supplement within the previous six months had a higher odd of CSO, compared to  
 223 those who took (AOR=1.91, 95% CI =1.19–3.07, P =0.007)  
 224

227 **Discussion**

228 Using a national representative sample of infants and young  
229 children, the current study aimed to determine the prevalence of  
230 CSO and its associated factors among infants and young children  
231 in Ethiopia. Our study provided evidence that there was co-  
232 occurrence of stunting and overweight among infants and young  
233 children in Ethiopia. We found CSO associated with factors at  
234 different levels. The basic factor associated with higher odds of  
235 CSO was being poor. The immediate factors found associated with  
236 higher odds of CSO were male sex, age above 12 months, small  
237 birth size and no vitamin A supplement use for the last six months.  
238 Our results showed high level of stunting among infants and young  
239 children, with 31.4% of children being stunted. Overweight was  
240 also prevalent, though not as high as stunting. We found that the  
241 2.45% of children concurrently suffered stunting and  
242 overweight/obese. There are studies that documented prevalence of  
243 co-occurrence of stunting and overweight among under five  
244 children in African countries. The prevalence determined by the  
245 current study was higher than studies compared to previous study  
246 conducted in Ghana that assessed dual burden of malnutrition  
247 among children younger than five years [22] but lower than a study  
248 conducted in South Africa and Libya that reported prevalence of  
249 18% and 7% respectively among under five children [15, 27].

250 Similarly, studies from Asia and Latin America countries  
251 determined the prevalence of concurrent of stunting and  
252 overweight. The prevalence of this report was within the range of  
253 report from Ecuador that reported a prevalence of 2.8% [10], higher  
254 than study from Mexico that reported a prevalence of 1% [16] and  
255 lower than a prevalence from China that reported 5.06% [21]. A  
256 recent study that examined the dual burden of malnutrition among  
257 children aged 6-59 months in the Middle-East and North Africa  
258 (MENA) and Latin American and Caribbean (LAC) regions also  
259 showed a prevalence that ranged from 0.4 to 10.7% in MENA  
260 regions and 0.3 to 1.9% in LAC regions [31]. The prevalence of  
261 current study is higher than prevalence of almost all LAC regions  
262 and within the range in most countries in MENA regions.

263 We also found several factors associated with CSO. Children of  
264 low household wealth were more likely to be concurrently stunted  
265 and overweight/obese. Children of low household wealth were  
266 more likely to be concurrently stunted and overweight/obese. This  
267 could be due to the fact that infant and young child caring practices  
268 like hygiene, proper feeding and health services utilization are  
269 often poorly practiced among poor households compared to their  
270 richer counterparts [32-34]. This finding also agrees with the  
271 existing literature on concurrent of stunting and overweight [22,  
272 25]. Children who reside in the rural areas had a higher risk of

273 being concurrently stunting and overweight though insignificant.

274 This finding was also consistent with the existing literature which

275 shows children residing in rural and less urbanized areas are at risk

276 of being concurrently stunted and overweight[21].

277 We also found higher odds of CSO in boys and those children

278 above 12 months of age. This could be due to fact that most

279 stunting occurs more during the period 12 to 23months of age[32,

280 35]. In general, children under-two years of age bear a higher

281 burden of both overweight and stunting, particularly in LMICs

282 countries[21]. Further, our finding of higher risks of CSO in boys

283 than in girls was not in agreement with previous reports which

284 demonstrated higher odds of stunting and overweight in girls [22].

285 Small birth size was also significantly associated with CSO. This

286 finding was also in agreement with the existing evidence which

287 suggests low birthweight linked to poor health and nutritional

288 outcomes [1, 35, 36]. Fetal growth restriction is an important

289 contributor to stunting in children and evidence showed that low

290 birthweight was associated with 2.5–3.5-fold higher odds of

291 wasting, stunting and underweight[36]. Further, other evidences

292 have suggested low birth weight babies who exhibit catchup

293 growth may be at risk of abnormal weight gain in childhood[37-

294 41]. In other words, intra uterine growth retardation might induce a

295 catch-up fat mass for the fetus before even born [42] and the rapid

296 weight gain appears to promote adiposity after about age 2 years  
297 particularly in LMICs [43]. Thus, it could be easily acknowledged  
298 that low birth weight child would be at a higher risk of being  
299 concurrently affected by stunting and overweight/obesity. Vitamin  
300 A intake was also associated with a significantly lower CSO  
301 prevalence. This would be most likely due to the role of vitamin A  
302 in promoting linear growth and reduce the risk of stunting[44-47].  
303 The first 1,000 days is a critical time for physical and intellectual  
304 growth and set a foundation for long term health and development  
305 [1]. As a result of greater awareness of significance of stunting as  
306 one of major public health problems, stunting reduction has gained  
307 increased international attention [48]. Similarly,  
308 overweight/obesity in this age group deserves attention because at  
309 early stage of life catch up growth have been identified as one of  
310 the risk factors that lead to progression of abnormal weight gain.  
311 [49-55]. Therefore, it is important to identify children that are at  
312 risk of developing CSO as early as possible to limit progression of  
313 both growth flattering and abnormal weight gain. Further, evidence  
314 have shown that if only under nutrition is targeted with an aim of  
315 targeting growth may unintentionally contribute to abnormal  
316 weight gain[56].  
317 The current study has the following limitations; first, recall bias  
318 while reporting the birth, infection, dietary history of children is

319 still an issue of concern [57]. In other words, collecting data like  
320 birth size, history of infection and dietary related data are solely  
321 based on memory of mothers or the caretaker which might have  
322 led to recall bias. Further, due to the cross-sectional nature of this  
323 study a cause and effect relationship could not be inferred.  
324 Given the above-mentioned limitations, the current work has some  
325 strengths. First, the EDHS data is a national representative data and  
326 conclusions about Ethiopia can be drawn. Second the data is  
327 reliable and of high quality since the standardized procedures are  
328 employed by such kind of survey. Third, appropriate statistical  
329 method was used to explore the relationships between the outcome  
330 variable and its determinants.

331

### 332 **Conclusion**

333 In conclusion, our study provided evidence on the co-existence of  
334 stunting and overweight/obesity among infants and young children  
335 in Ethiopia. CSO was associated with various factors originating  
336 from community and child levels. Therefore, identifying children  
337 at risk of growth flatter and excess weight gain provides IYCF  
338 programs in Ethiopia and beyond with an opportunity of earlier  
339 interventions.

340 **Abbreviations:**

341	AOR	Adjusted Odds Ratio
342	BAZ	Body Mass Index for Age Z-score
343	BMI	Body Mass Index
344	CI	Confidence Interval
345	CSO	Concurrent of Stunting and Overweight/Obesity
346	EA	Enumeration Area
347	EDHS	Ethiopia Demographic and Health Survey
348	IYCF	Infant and Young Child Feeding
349	LAZ	Length for Age Z-score

370 **Availability of data and materials**

371 The dataset for this study is available from the corresponding

372 author on reasonable request.

373 **Ethical approval**

374 Ethical clearance for the survey was provided by Institutional

375 Review Board (IRB) of the College of Medicine and Health

376 Sciences at Jigjiga University. Online application to analyze the

377 secondary data was requested from DHS Program, USAID and we

378 have been authorized to download data from the Demographic and  
379 Health Surveys (DHS) online archive.
