24

25 **Abstract**

26 **Background:** In March 2020, overall, 37,000 international students from the country at risk
27 of the 2019-novel coronavirus (COVID-19) infection will arrive in Seoul, South Korea.
28 Individuals from the country at risk of COVID-19 infection have been included in a home-
29 quarantine program, but the efficacy of the program is uncertain.

30 **Methods:** To estimate the possible number of infected individuals within the large influx of
31 international students, we used a deterministic compartmental model for epidemic and
32 perform a simulation-based search of different rates of compliance with home-quarantine.

33 **Results:** Under the home-quarantine program, the total number of the infected individuals
34 would reach 24–53 from March 17–March 20, 50–86 from March 18– March 16, and 234–
35 343 from March 4– March 23 with the arrival of 0.1%, 0.2%, and 1% of pre-infectious
36 individuals, in Seoul, South Korea, respectively. Our findings indicated when incoming
37 international students showed strict compliance with quarantine, epidemics were less likely to
38 occur in Seoul, South Korea.

39 **Conclusion:** To mitigate possible epidemics, additional efforts to improve the compliance of
40 home-quarantine are warranted along with other containment policies.

45 **BACKGROUND**

46 Three major respiratory virus-related events have been observed in South Korea in the 21st
47 century: severe acute respiratory virus (SARS), Middle East respiratory syndrome, and the
48 2019-novel coronavirus (COVID-19) infection, all of which are caused by members of the
49 coronavirus family. The first individual with COVID-19 infection in South Korea was
50 identified on January 20, 2020 and, the number of laboratory-confirmed cases increased
51 between then and February 12, 2020 [1]. To reduce the number of individuals entering South
52 Korea who may have been exposed to COVID-19 in Wuhan, China, an international travel
53 ban from Hubei Province, China to South Korea was implemented on February 3, 2020
54 (Figure 1) [2]. Furthermore, to identify individuals who may have been exposed to COVID-
55 19, the South Korean public health authority implemented a quarantine program. Any persons
56 who have travelled from a country with COVID-19 infection risk within the previous 14 days
57 or have been in contact with laboratory-confirmed COVID-19 infection within the previous
58 14 days is defined as an individual for quarantine [3]. Quarantined individuals are asked to
59 comply with home-quarantine and are monitored by local public health workers twice a day
60 for 14 days after contact with individuals with infection [3].

61 On February 14, 2020, the South Korean public health authority identified an
62 individual with COVID-19 infection; the patient had been contacted by another individual
63 who was suspected of avoiding the quarantine program during his period of home-quarantine
64 [4]. According to previous literature, the effectiveness of quarantine varies widely depending
65 on individuals' daily motility patterns [5]; Despite this compliance with home-quarantine in
66 the present instance is still in question.

67 It is important to note that 37,000 students from China, where major cities are likely
68 experiencing localized outbreaks [6], will enter Seoul, South Korea, on March 1, 2020 at the

69 start of the spring semester. This large number of incoming youths from the country with
70 COVID-19 infection risk may increase the risk of local transmission in South Korea.

71 In this study, we aimed to estimate the number of infected individuals in Seoul, South Korea,
72 based on compliance with home-quarantine among these incoming international students.

73

74 **METHODS**

75 To simulate possible epidemics, we used the deterministic compartmental model of the
76 susceptible-exposed-infectious-removed type (see the Supplementary Appendix). We
77 assumed that the population mixed homogeneously, and that no COVID-19 transmission had
78 occurred within the community in Seoul, South Korea. We assumed that either 0.1%, 0.2%,
79 or 1% of the incoming international students were in the pre-infectious period of COVID-19
80 infection, based on previous literature reporting that 0.2% of individuals with contactees of
81 SARS infection were asymptomatic [7]. We also assumed that the international students
82 would arrive in Seoul, South Korea in the 15 days before and after March 1, 2020, and that
83 no individuals were isolated during entry screening upon arrival. Furthermore, we assumed
84 that all quarantined individuals were confined at home or to the university dormitory as per
85 the current South Korean quarantine program for COVID-19 infection implemented by the
86 local public health authority. The baseline scenarios were based on the currently identified
87 number of infected persons from China in South Korea, which was 12 on February 6, 2020,
88 with the assumption of 90% compliance with home-quarantine during the pre-infectious
89 period. Scenarios with different quarantine compliance rates (70%, 80%, or 90%) among
90 these international students were also modeled. We considered a time horizon of 180 days for
91 the number of individuals infected and quarantined since January 20, 2020, when the first
92 COVID-19 case was identified in South Korea. The parameter values of our model, obtained

93 from previous studies, are shown in the Supplement Material.

94

95 **RESULTS**

96 We estimated that the total number of infected individuals would reach 24–53 from March
97 17–March 20, 50–86 from March 18–March 16, and 234–343 from March 4–March 23 with
98 the arrival of 0.1%, 0.2%, and 1% of pre-infectious individuals, in Seoul, South Korea,
99 respectively (Figure 2).

100 We also estimated that the number of individuals isolated from the South Korean
101 quarantine program would peak at 24–47 from March 17–March 25, 48–77 from March 16–
102 March 28, and 225–305 from March 14–March 25 with the arrival of 0.1%, 0.2%, and 1% of
103 pre-infectious individuals in Seoul, South Korea, respectively (Figure 3). The number of
104 infected and isolated individuals would increase with higher proportions of subclinical
105 COVID-19 cases. However, the number of infected and isolated individuals was smaller due
106 to the high compliance of the quarantine program.

107

108 **DISCUSSION**

109 When no effective vaccine or treatment is available for infectious disease, the quarantine of
110 individuals suspected of having the infection, including those exposed to infection from
111 epidemic countries, has been used as a mitigation strategy by public health authorities [8, 9].

112 The number of laboratory-confirmed individuals with COVID-19 infection is
113 increasing in China and other Asian countries. In South Korea, the likelihood of local
114 transmission is increasing because travelers are arriving from COVID-19-affected countries.

115 The quarantine of individuals who may have been exposed to COVID-19 is an efficient
116 public health strategy, to reducing transmission while using limited public health resources,

117 because the presence of individuals with unidentified infection is highly likely among
118 individuals exposed to the infectious diseases [9]. Therefore, the number of individuals with
119 infection can be estimated based on compliance with home-quarantine to provide relevant
120 evidence for public health authorities and to improve international students' compliance with
121 the quarantine program in advance.

122 In South Korea, individuals who had contacted a person with infection were asked to
123 comply with home-quarantine and were monitored by local public health workers twice a day
124 for 14 days post-contact [3]. Individuals who were not included in the quarantine program but
125 had experienced any possible contact were encouraged to notify public health authorities and
126 submit to quarantine. All daily necessities were provided to all quarantined individuals by the
127 public health authorities to avoid possible contact with any susceptible population, as
128 indicated by the South Korean law. Therefore, the current quarantine program in South Korea
129 is very broad and includes a large number of people. However, to relieve the pressure on
130 public health resources, the quarantine program for incoming international students will be
131 monitored by the education authority [10]. This may affect the efficacy of quarantine and
132 increase the number of infected and isolated individuals.

133 Our findings indicate that most of the infected individuals isolated from the home-
134 quarantine program; Therefore, epidemics by incoming international students are unlikely to
135 occur in Seoul, South Korea; However, the number of infected and isolated individuals could
136 increase by mid or late March. Furthermore, the quarantine program may consume a large
137 number of public health resources because it involves monitoring quarantined individuals and
138 isolating infected individuals.

139 The present study had several limitations. Firstly, some parameters including the
140 latent period and rate of infection among those in contact with a person with infection were

141 obtained from the modelling studies of COVID-19 [6, 11, 12], and consequently may revise
142 the results. Secondly, we used a deterministic model, and can't evaluate the uncertainty of
143 these estimates, which is an inherent feature and missed under current analysis. However,
144 allowing a search of different plausible values of these parameters through this model
145 simulation approach, ensures the reliable parameter estimates and able to mimic the future
146 dynamics of the number of infected individuals, which is much smaller than the total
147 population [13]. Thirdly, we did not consider transmission that occurred before symptom
148 onset and did not account for subclinical infection.

149

150 **CONCLUSIONS**

151 As public health resources are limited, quarantine of individuals who may have been exposed
152 to infectious disease is crucial for preventing local transmission [14]. Therefore, strict home-
153 quarantine of individuals from countries at risk for COVID-19 infection is important to
154 reduce the number of infected individuals and to prevent possible epidemics in the
155 community.
