36 **Abstract :**

37 After SARS-CoV-2 set foot in India, the Indian Government took a number of steps to limit the  
38 spread of the disease in the country. This study involves assessing how the disease affected the  
39 population in the initial days of the epidemic. Data was collected from government controlled  
40 and crowdsourced websites and then put through analysis and calculations. With a study on age  
41 and sex parameters of 413 patients, the median age of the affected individuals was found out to  
42 be 36 years (IQR 25-54 years) with 20-39 years males being the most affected group. The  
43 number of affected males (66.34%) was more than that of the females(33.66%).Using SIR  
44 model, the range of contact rate( $\beta$ ) of India was calculated and the role of public health

45 interventions was assessed which proved that the interventions were effective for a little while  
46 but the effect reduced due to violations.

#### 47 **INTRODUCTION:**

48 In December 2019, a cluster of patients with pneumonia of unknown origin was encountered in  
49 Wuhan, China (1). The causative agent was determined to be a novel virus of the *Coronaviridae*  
50 family of RNA viruses and was claimed to be of zoonotic origin (1). Due to its close relationship  
51 with the SARS-CoV, this novel coronavirus was named SARS-CoV-2 (2). Since then, SARS-  
52 CoV-2 has caused a widespread outbreak of the disease now known as COVID-19 and was  
53 declared to be a pandemic by WHO on March 11 2020 (3). Human to human transmission occurs  
54 primarily through close-contact with the infected person, through fomites in the immediate  
55 surroundings of the infected person and via droplets of respiratory secretions (4, 5), although  
56 there is some evidence pointing to a possibility of airborne and faeco-oral transmission as well  
57 (6, 7). According to few case studies, transmission may also occur via viral shedding in “pre-  
58 symptomatic” individuals during the incubation period (8, 9).

59 The incubation period for COVID-19 is thought to be within 14 days of exposure, with a median  
60 incubation period of 4-5 days (4, 10, and 11). The median age of patients affected by COVID-19  
61 is 47 years with the most common clinical findings being fever and cough (4, 12). Other  
62 symptoms include expectoration, headache, myalgia fatigue, and diarrhoea and haemoptysis in  
63 rare cases. About 18% of patients develop shortness of breath (4). Severe disease has been  
64 shown to occur in 14% of patients with older age and pre-existing chronic disease being risk  
65 factors for severe disease (4, 13). Critical disease requiring intensive care unit admission has  
66 been reported in 5 percent, and overall case-fatality rate as 2.3% (13). Currently, there are no  
67 approved treatments for COVID-19 and clinical trials such as the WHO SOLIDARITY trial are

68 underway to evaluate the effectiveness of drugs like lopinavir-ritonavir, remdesivir,  
69 hydroxychloroquine and azithromycin (3, 14).

70  
71 India reported its first case of COVID-19 on 30 January, 2020; a medical student who had  
72 travelled from Wuhan, China, the then epicenter of COVID-19 (15). While there were only a few  
73 reported imported cases in the month of February, the number began to increase rapidly in March  
74 (14). On 15th March 2020, India sealed its borders and stopped all international flights, meaning  
75 all the initial imported cases which seeded COVID-19 in India arrived in the Indian subcontinent  
76 before 15 March 2020 (16). According to the data available in the public domain, India had  
77 approximately 3726 cases (both imported cases and due to person-to-person transmission) as of 5  
78 April 2020 (17). According to the Indian Council of Medical Research, as of 31st March 2020,  
79 community transmission has not yet started and India is in category 2 of WHO classification for  
80 transmission patterns, i.e., sporadic cases without evidence of community transmission (18).

81  
82 The most important question in the current scenario concerns the mathematical parameters of the  
83 initial spread of COVID-19 in India, and what are the epidemiological aspects that can predict  
84 this spread. We acknowledge there are certain difficulties in making precise calculations due to  
85 the rapidly changing dynamic of the epidemic in the early stages, limited availability of data in  
86 the public domain, absence of robust line listing of cases and limited testing capacity.

87 Nonetheless, mathematical models with reasonable assumptions based on available information  
88 can help in analysis of the currently available data to provide important insights for guiding  
89 public health interventions. For a predictive model to be relevant to the reality, the model itself  
90 should represent what is happening in the real world. The most basic of these models is the SIR

91 (susceptible-infected-removed) model (19,20), which we've used in the current Indian scenario  
92 to determine the range in which contact rate  $\beta$  lies and also calculate the range of the current  
93 reproduction number,  $R_t$ .

94 In the first part of our paper, we outline the several public health measures taken by India in  
95 response to the COVID-19 outbreak. We then study and analyze the epidemiological parameters  
96 of COVID-19 in India using publicly available data till 28 March 2020. Finally, we use the SIR  
97 model, and run simulations to determine the effective contact rate  $\beta$ , and derive from that the  
98 reproduction number  $R_t$ , and comment on the result of the nationwide public health measures  
99 implemented from mid-March 2020 and the lockdown implemented from 25 March 2020.

#### 100 **INDIA'S OUTBREAK RESPONSE:**

101 Since the beginning of the outbreak in India, there have been a number of interventions done at  
102 various levels by the state governments and by the Central Government agencies. The number of  
103 cases started increasing in March (21), prompting a number of interventions to control the  
104 outbreak. The first interventions were mostly related to travel advisories and bans. Gradually  
105 there were more social distancing measures in March which were then followed by lockdowns,  
106 ultimately culminating in a nation-wide 21 day lockdown from 25 March, 2020 (Table 1)

#### 107 **METHODS:**

##### 108 **Epidemiological analysis:**

109 **Data Source-** The raw data was collected from the patient database of covid19india.org which is  
110 a crowdsourced patient database for positive cases of SARS-CoV-2 which have been confirmed  
111 by laboratory testing, including data from state government and central government agencies  
112 (<https://www.covid19india.org/>). The data was taken for cases confirmed on 28 March, 2020 or  
113 earlier. Only those patient data were analyzed which had both age and sex data of the patient

114 mentioned. For convenience of analysis, patients whose age data was given as a range were  
115 excluded.

116 **Study population** - The above method yielded a sample of size  $n=413$ . Of these patients, the  
117 status of the patient as of 28th March 2020 was not known for 13 patients.

118 **Study Design** - For the epidemiological analysis part of the study, we used a descriptive design.  
119 After collecting the data analysis was done in regard to the age distribution, status of patients and  
120 sex distribution using Microsoft Office Excel 2007. Fatality ratio in any category was found out  
121 by dividing the number of deaths in the category by the number of affected individuals of that  
122 category. Central tendencies for age of patients of various categories were also calculated.

### 123 **Mathematical analysis:**

124 **Study Design-** The transmission rate  $\beta$  is used to describe the flow of individuals in a population  
125 going from a susceptible state to an infected state, and it is important to obtain a realistic estimate  
126 of the transmission rates in order to create useful and realistic simulation models for decision  
127 support. Accurate estimation of this rate is important because it can have a major influence on  
128 disease predictions and conclusions.

129 We have used the data available till 4th April to estimate the two parameters,  $\beta$  and  $R_t$  (time  
130 varying reproductive number) used in the SIR model ([www.statista.com](http://www.statista.com)). We assumed that the  
131 recovery rate  $\gamma$  would remain constant for the population. We plotted the  $\gamma$  distribution curve till  
132 3rd April and took the mean value of  $\gamma$ . Since the effect of interventions would reflect in the  
133 contact rate  $\beta$ , we then took the value of  $\gamma$  to be constant equal to the mean and ran the SIR  
134 model multiple times by varying the value of  $\beta$ , and comparing the trends with the real data. We  
135 plotted the trendline for the real data using Microsoft Office Excel 2007, and used the equation

136 of the curve to find out the trend of  $\beta$  in India in the present day scenario by comparing it to  
137 equation 4.

138

139 The spread of a disease in the population is studied by the SIR model (19,20) which divides the  
140 (fixed) population of  $N$  individuals into three "compartments" which vary as a function of time  
141 (For purposes of this study, we have not included vital dynamics like birth and death rate.) -

142

- 143 •  $S(t)$  -  $S(t)$  are those susceptible but not yet infected with the disease (in a novel disease  
144 like nCOV-19, the entire population is assumed to be susceptible as there is no pre-existing  
145 immunity);
- 146 •  $I(t)$  -  $I(t)$  is the number of infectious individuals;
- 147 •  $R(t)$  -  $R(t)$  are those individuals who have been removed from the infected  
148 population (includes those who have recovered from the disease and also the deaths)

149

150 The SIR model describes the change in the population of each of these compartments in terms of  
151 two parameters,  $\beta$  and  $\gamma$ .

152  $\beta$  -  $\beta$  describes the effective *contact rate* of the disease: a susceptible individual comes into  
153 contact with an infectious individual and acquires the disease. This parameter takes into account  
154 both the number of people contacted per unit time, and the effectiveness of transmission in each  
155 contact.

156  $\gamma$  -  $\gamma$  is the mean *removal rate*: In our model, it is calculated using the removed cases as against  
157 the new cases on a daily basis.

158  $\beta$  and  $\gamma$  are useful in the SIR model using the following differential equations-

159 
$$dS/dt = -\beta SI/N \dots\dots[1]$$

160 
$$dI/dt = \beta SI/N - \gamma I \dots\dots[2]$$

161 
$$dR/dt = \gamma I \dots\dots\dots[3]$$

162 Assuming the present scenario in India where  $I \ll N$  and  $R \ll N$ ,  $S$  is almost equal to  $N$ . So  $S/N=1$ .

163 Putting this in equation 2 and integrating, we get

164 
$$I(t) = Ae^{(\beta-\gamma)t} \dots\dots[4]$$

165 Where  $A$  is determined the number of cases at  $t=0$ .

166 **Study setting-**  $\beta$ , the effective *contact rate* reflects the force of infection of the disease. It is  
167 time-varying, and helps us understand at what rate the epidemic is progressing. We have  
168 analyzed the data from the initial period of the COVID epidemic in India, till 4 April 2020 and  
169 calculated the  $\beta$  and the  $R_t$  for the same.

170 **Data variables, Sources and Analysis-**  $\gamma$  was calculated to be 0.103(the removal rate followed  
171 a normal distribution, and the mean was calculated with the data available from 01 March to  
172 April 04 2020) (22).

173

174 **RESULTS:**

175 **Epidemiological parameters:**

176 The patients affected in India had a median age of 36 years with IQR of 25-54 years. Largest  
177 percentage of affected patients was in the age group of 20-39 years. There were 66.34% male  
178 patients and 33.66% female patients. The median age for affected males was 35 years (IQR 25-  
179 50) and for females was 40 years (IQR 24.5-59). Both in male patients and female patients the  
180 largest number of affected patients was in the 20-39 years age group accounting for 54.38% of

181 males and 41.01% of females. This was followed by the age group 40-59 years accounting for  
182 25.91% of males and 26.62% of females. According to the data, 16 patients out of 413 had died  
183 accounting for 3.8 % cases, with 68.75% of all the deaths among 60-79 years, accounting for 11  
184 deaths. The median age of deceased patients was 65 years with IQR 59.25-69. The mortality rate  
185 in male patients was 4.38% and for female patients was 2.88%.

186 For recovered patients, most were in the 20-39 age group followed by the 40-59 years age group.  
187 Median 36 years with IQR 21.75-56.25. As per the data as on 28 March, 2020, 14 of these 413  
188 patients had recovered.

189 The number of hospitalized patients accounted for 370 of the 413 patients. However, status of 13  
190 of the 413 patients was not available.

191 Table 3 gives the current status of patients across age and sex, and Table 2 gives the age and  
192 gender distribution with normalized values with respect to percentage in Indian population.

### 193 **Mathematical analysis:**

194 After running multiple simulations, all assuming different values of  $\beta$ , we found that the value of  
195  $\beta$  in the current India scenario calculated from the trendline of real data lies around 0.258. ,  
196 which is also visible in the graph of real-time active cases lying between 0.24 and 0.29 (Figure  
197 3).

198 Also visible in the graph, is the real data line shifting from 0.24 to 0.28 from day 8. Also, as  $R_t =$   
199  $\beta/\gamma$ , the value of the Reproduction number is found to be varying between 2.4-2.9 in the Indian  
200 scenario until 4th April 2020.

201 Considering the present trend of  $\beta$ , India can have more than 9700 active cases by the end of the  
202 21 day lockdown.

### 203 **DISCUSSION:**

204 The median age of affected patients in our study sample of 413 was 36 years(IQR 25-54)with the  
205 median age for female patients (40 years, IQR 24.5-59) was more than that of male patients  
206 (Median age 35 years, IQR 25-50). In study cohorts of Wuhan, the median age of affected  
207 patients range from 49-56 years (4, 23, 24). Thus, there are more people affected at a lower age  
208 in India when compared to China. This observation can be explained by the population  
209 distribution of India. In previous studies on COVID 19, it has been established that the risk  
210 increases with age and comorbidities (13, 23, 24). However, according to the population  
211 demographics in India for 2020 (36), the broad based nature of India's population pyramid  
212 means there are more people in the younger age group category and very few people in the above  
213 80 years age group category.This is reflected in the number of cases which are more in the  
214 younger age groups. On normalizing the percentage of patients in each age group with the  
215 corresponding percentage representation of the population, we observed that the highest number  
216 of male patients is in the 20-39 years age group category. Interestingly, according to this  
217 analysis, males in the 20-39 years age group are more affected than even the 60-79 years age  
218 group males or above 80 years age group males. This is something that has not been reported  
219 until now and it has to be seen whether this changes as the number of cases in India grows.  
220 Similarly finding the normalized ratio of affected patients by age group shows that for females,  
221 above 80 years age group is more affected. On the same lines the mortality rate due to the  
222 disease was found to be lower as compared to other countries.

223 As of 30 March, 2020, India has still not officially reported community spread (25). So the cases  
224 now are people who were affected in foreign countries or their direct contacts. In 2018, Indian  
225 residents between 35 and 49 years of age took the most holidays outside the nation (26). So, it is

226 also possible that the number of young patients is more in India than other countries because they  
227 constitute the majority of outbound tourists. If community spread begins, this can get altered.

228 Another consideration in this regard are the comorbidities in the Indian population because  
229 hypertension, COPD, neoplasms have been related to higher risk of infection by SARS-Cov 2. In  
230 a 2016 Global Burden of Disease Study in the Indian population (27), it was found that diseases  
231 like cardiovascular diseases, chronic respiratory diseases, and neoplasms were as prevalent in the  
232 40-69 yrs age group as older age groups. Hence, this can be another reason for the lower median  
233 patient age in India.

234

235 The present data gives a case fatality rate of 4.38% for males and 2.88% for females. In China,  
236 the case fatality rate was found as 2.3% with 1023 deaths of 44672 confirmed cases, 14.8% in  
237 the above 80 years population, and 8.0% in the 70-79 years population (13). Our estimate gives a  
238 higher value which may be due a smaller sample size or can also be because mild cases of  
239 COVID 19 have so far been missed due to limited testing capacities in India. In our study, there  
240 is a 16.18% mortality rate in 60-79 years age group and 20.0% in above 80% age group. These  
241 may be an underestimation or overestimation of the actual mortality rate as the total number of  
242 deaths is still small and many are still hospitalized. The mean age of the deceased males and  
243 females implies male patients of younger age have higher risk of death than females of similar  
244 age. The mean age for recovered patients is lower than the mean ages for the deceased implying  
245 younger patients have a higher chance of recovery. These are in accordance with findings from  
246 other countries (13, 28). If we consider all the patients, males account for 66.34% of patients,  
247 implying more males are generally affected. 75.0% of the deceased were also males which show  
248 that males are more vulnerable agreeing with previous studies (29, 30).The explanation for a

249 lower mortality rate due to CoVID infection than that of other countries [worldometer.org],  
250 could also be the universal immunisation policy against BCG (31).  
251 The value of the  $\beta$  being 0.258 (range between 2.4-2.9) and the trend for  $R_t$  being about 2.50,  
252 shows that the interventions which were put in place by the Indian government (assuming a lag  
253 period of 11 days) during the mid-March period were partially effective, preventing the scenario  
254 where  $R_t$  can reach even more than 4 (32), and further data would tell how effective the  
255 lockdown is. The increase in  $\beta$  from day 8 is probably due to the identification of the Tablighi  
256 cluster and the cases it added to the Indian data (33).

257  
258 According to a study (32) in the early days of the epidemic, Wuhan city and Hubei province  
259 showed  $R_t$  between 1.85 and 4.46 which matches our study. All over China, the  $R_t$  varied from  
260 1.23 to 5.77. South Korea which has high population density like India had a decreasing trend of  
261  $R_t$  from 9.72 on 20 February to 1.50 on 7 March. This indicates that the interventions have been  
262 helpful in preventing the worst case scenario in India but is unable to prevent the spike in  
263 number of cases (33,34). The situation can still be controlled if  $R_t$  can be brought down close to  
264 1. This indicates the need for severe interventions required and ensuring optimum testing to avoid  
265 underestimation of danger.

266 The impact of the COVID-19 response ( overall quarantine regulations , social distancing, and  
267 isolation of infections) in China in this context is encouraging for the many other countries (35)  
268 where the  $R_t$  gradually stabilized for most provinces ranging between 0.96 to 1.57 where there  
269 were more than 100 cases (32), and India should try and replicate this when community  
270 transmission starts by strict enforcement of lockdown measures to get the  $R_t$  closer to 1, so that  
271 COVID would not overwhelm the Indian healthcare system. The Indian government will not be

272 able to minimise both deaths from coronavirus disease 2019 (COVID-19) and the economic  
273 impact of viral spread. Keeping mortality as low as possible will be the highest priority for  
274 individuals; hence the Indian government must put in place measures to ameliorate the inevitable  
275 economic downturn (36). However the Indian government's timely decision to put a country  
276 wide lockdown into place when the number of cases was documented to be only 415, and  
277 effective contact tracing definitely helped to reduce the  $R_t$  and prevent an Italy/US like situation  
278 (however in the context of violations of the lockdown, more data awaited).

## 279 **LIMITATIONS**

280 The lack of enough kits for testing at the beginning of the outbreak among other logistic and  
281 political reasons was one of the major issues. The Indian government tried to correct these issues  
282 by altering the criteria for testing on 21 March 2020. However, it undermines the quality of data  
283 collected in the early phase of the epidemic. We have used crowd sourced data from  
284 covid19india.org due to lack of availability of official data. Even though the number of cases in  
285 India till 28 March was more, we could not include all the cases due to unavailability of the  
286 demographic details of all the patients. If these details along with the clinical details as well are  
287 released, further studies can help in better assessment of the disease course. Also, it could help  
288 the government with better interventions to control the spread of the disease.

433 **Table 1: Interventions done at the central government or state level in India to control the**  
 434 **COVID 19 outbreak till 27 March, 2020 (Source : [MoHFW](#))\***

Date	Intervention	Category
17-01-2020	First travel advisory to people visiting China to observe specific guidelines	Movement Restriction
24-01-2020	Guidance for sample Collection, Packaging and Transportation for Novel Coronavirus released	Public Health Measures
25-01-2020	Guidance on Surveillance for human infection with 2019-nCoV released	Public Health Measures
	Second travel advisory issued	Movement Restriction
01-02-2020	324 people evacuated from Wuhan by India	Evacuation
02-02-2020	323 Indians evacuated from Wuhan by India	Evacuation
05-02-2020	Travel advisory to China with quarantine warning for 15 Jan onwards, E-visas to China suspended	Movement Restriction
18-02-2020	Thermal screening starts at major international airports in India	Public Health Measures
26-02-2020	Travel advisory that travellers from China have to be quarantined	Movement Restriction

<b>27-02-2020</b>	Third evacuation from Wuhan by India	Evacuation
<b>03-03-2020</b>	Central government suspended the issuing of new visas and visas already issued for nationals of Italy, Iran, South Korea, and Japan	Movement Restriction
<b>04-03-2020</b>	The Minister of Health and Family Welfare, Dr. Harsh Vardhan, announced compulsory screening of all international passengers arriving in India. Universal surveillance of international passengers started.	Public Health Measures
<b>05-03-2020</b>	Primary school shut in Delhi; Government advisory on avoiding mass gatherings	Social Distancing
<b>06-03-2020</b>	Government advisory for Exemption to mark biometric attendance in AEBAS released	Public Health Measures
<b>07-03-2020</b>	Primary schools in Jammu and Kashmir shut after two cases with 'suspected high viral load	Social Distancing
<b>09-03-2020</b>	Manipur, Mizoram close international borders; Qatar bans travel to India	Movement Restriction
	Karnataka, Kerala declare holidays for educational institutions	Social Distancing
	ICMR testing strategy released to test symptomatic people with travel history or contact history	Public Health Measures
<b>10-03-2020</b>	Travel advisory regarding home quarantine on return from affected	Movement Related

	countries	
	SOP for international cruise ships at major ports released	Public Health Measures
<b>11-03-2020</b>	Cabinet Secretary of India announced that all states and Union Territories should invoke provisions of Section 2 of the Epidemic Diseases Act, 1897	Public Health Measures
	The Indian government suspended all visas to India effective from 12:00 GMT on 13 March 2020 except diplomatic, official, United Nations/International organisations, employment and project visas till 15 April 2020. suspended visa free travel for OCI card holders and Indians coming from COVID hit nations quarantined for 14 days	Movement Restriction
	Guidelines for home quarantine by citizens released	Social Distancing
	Guidelines on use of mask by public	Public Health Measures
<b>12-03-2020</b>	Schools shut in Delhi	Social Distancing
	Public places to be disinfected in Delhi	Public Health Measures
<b>13-03-2020</b>	The Government of India suspended all international passenger	Movement

	traffic in and out of Indo-Bangladesh, Indo-Nepal, Indo-Bhutan and Indo-Myanmar border check posts.	Restriction
	Gazette Notification - Essential Commodities Order, 2020 - with regards to Masks and Hand Sanitizers released	Public Health Measures
<b>14-03-2020</b>	Central government declared the pandemic as a "notified disaster" under the Disaster Management Act, 2005, enabling states to spend a larger part of funds from the State Disaster Response Fund (SDRF) to fight the virus	Public Health Measures
<b>15-03-2020</b>	Guidelines on dead body management released	Public Health Measures
<b>16-03-2020</b>	Advisory on social distancing released	Social Distancing
	Indo-Pakistan checkpoints closed; the entry of travelers from the European Union, United Kingdom and Turkey banned	Movement Restriction
<b>17-03-2020</b>	Indian states with high footfall of international tourists like Sikkim start banning entry of tourists and ask existing tourists to leave (other states like Himachal Pradesh, Uttarakhand follow suit); quarantine of passengers from United Arab Emirates, Qatar, Oman, Kuwait	Movement Restriction
	Monuments like Taj Mahal closed by Archaeological Survey of	Social Distancing
