20 **Abstract**

21 Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) has caused more than
22 200,000 reported COVID-19 cases in Spain resulting in more than 20,800 deaths as of
23 April 21, 2020. Faecal shedding of SARS-CoV-2 RNA from COVID-19 patients has
24 extensively been reported. Therefore, we investigated the occurrence of SARS-CoV-2
25 RNA in six wastewater treatments plants (WWTPs) serving the major municipalities
26 within the Region of Murcia (Spain), a low prevalence area. Firstly, an aluminum
27 hydroxide adsorption-precipitation concentration method was tested using a porcine
28 coronavirus (Porcine Epidemic Diarrhea Virus, PEDV) and mengovirus (MgV). The
29 procedure resulted in average recoveries of $10.90 \pm 3.54\%$ and $10.85 \pm 2.11\%$ in influent
30 water and $3.29 \pm 1.58\%$ and $6.19 \pm 1.00\%$ in effluent water samples for PEDV and MgV,
31 respectively. Then, the method was used to monitor the occurrence of SARS-CoV-2 from
32 March 12 to April 14, 2020 in influent, secondary and tertiary effluent water samples. By
33 using the real-time RT-PCR (RT-qPCR) Diagnostic Panel validated by US CDC that
34 targets three regions of the virus nucleocapsid (N) gene, we estimated quantification of
35 SARS-CoV-2 RNA titers in untreated wastewater waters of $5.29 \log$ genomic copies/L
36 on average. Moreover, we tested as negative all secondary and tertiary treated water
37 samples, highlighting that current water disinfection treatments applied in the analyzed
38 WWTP are able to remove SARS-CoV-2 RNA.

39 This environmental surveillance data were compared to declared COVID-19 cases at
40 municipality level, revealing that SARS-CoV-2 was circulating among the population
41 even before the first cases were reported by local or national authorities in many of the
42 cities where wastewaters have been sampled. The detection of SARS-CoV-2 in
43 wastewater in early stages of the spread of COVID-19 highlights the relevance of this
44 strategy as an early indicator of the infection within a specific population. At this point,

45 this environmental surveillance could be implemented by municipalities right away as a
46 tool, designed to help authorities to coordinate the exit strategy to gradually lift its
47 coronavirus lockdown.

50 concentration protocol, RNA virus.

51 **1. Introduction**

52 Coronaviruses (CoVs) are a family of viruses pathogenic for humans and animals
53 associated to respiratory and gastro-intestinal infections. CoVs used to be considered as
54 minor pathogens for humans as they were responsible of common cold or mild respiratory
55 infections in immunocompetent people. Nonetheless, the emergence of novel and highly
56 pathogenic zoonotic diseases caused by CoVs such as Severe Acute Respiratory
57 Syndrome (SARS), Middle East Respiratory Syndrome (MERS) and most recently
58 SARS-CoV-2 arises questions to be addressed to guide public health response.

59 CoVs are mainly transmitted through respiratory droplets. However, as for SARS and
60 MERS, SARS-CoV-2 RNA has been detected in stool samples from patients suffering
61 COVID-19 and from asymptomatic carriers (1–5). The duration of viral shedding has
62 been observed to vary among patients with means of 14-21 days (6, 7), as well as the
63 magnitude of shedding varies from 10^2 up to 10^8 RNA copies per gram (1, 2, 8).

64 Infectious viruses deriving from fecal specimen have been cultured in Vero E6 cells and
65 observed by electron microscopy (9). In addition, gastric, duodenal, and rectal epithelial
66 cells are infected by SARS-CoV-2 and the release of the infectious virions to the
67 gastrointestinal tract supports the possible fecal-oral transmission route (10). Even though
68 the possibility of faecal-oral transmission has been hypothesized, the role of secretions in
69 the spreading of the disease is not clarified yet (6, 7, 9, 11).

70 Wastewater monitoring has been a successful strategy pursued to track chemical and
71 biological markers of human activity including illicit drugs consumption,
72 pharmaceuticals use/abuse, water pollution, and occurrence of antimicrobial resistance
73 genes (12–15). Viral diseases have been also surveilled by the detection of genetic
74 material into wastewater as for enteric viruses (16–18), re-emerging zoonotic hepatitis E
75 virus (19, 20), and poliovirus during the global eradication programme (21).

76 Currently, various studies detected SARS-CoV-2 RNA in wastewater worldwide (22–
77 26), and wastewater testing has been suggested as a non-invasive early-warning tool for
78 monitoring the status and trend of COVID-19 infection and as an instrument for tuning
79 public health response (27–29). Under current circumstance, this environmental
80 surveillance could be implemented in wastewater treatment plants as a tool, designed to
81 help authorities to coordinate the exit strategy to gradually lift its coronavirus lockdown.
82 Here, we report the first detection of SARS-CoV-2 RNA in untreated wastewater samples
83 in Spain collected from six different wastewater treatment plants (WWTPs) in Murcia,
84 the lowest prevalence area in Iberian Peninsula. Additionally, the efficacy of the
85 secondary and tertiary treatments implemented in the WWTPs against SARS-CoV-2 has
86 been confirmed. The outcomes of the environmental surveillance reflect the
87 epidemiological data in a low COVID-19 diagnosed cases setting, thus supporting the
88 need of developing and implementing advanced models for wastewater-based
89 epidemiology (WBE).

90 **2. Material and methods**

91 **2.1. Sampling sites and samples collection**

92 Influent and effluent water samples were collected from six WWTPs located in the main
93 cities of the Region of Murcia, Spain (Figure 1). Technical data on WWTPs are
94 provided in Table 1.

95 A total of 42 influent, and 18 secondary and 12 tertiary treated effluent water samples
96 were collected from 12 March to 14 April 2020 and investigated for the occurrence of
97 SARS-CoV-2 RNA. Collected samples were transferred on ice to the laboratory and
98 concentrated on the same day of sampling or the day after.

99

100 **2.2. Wastewater and effluent water concentration**

101 The porcine epidemic diarrhea virus (PEDV) strain CV777 and the mengovirus (MgV)
102 vMC0 (CECT 100000) were preliminary used to evaluate the aluminum hydroxide
103 adsorption-precipitation method previously described for concentrating enteric viruses
104 from wastewater and effluent water (30, 31). In brief, 200 mL of biobanked influent (n=2)
105 and effluent water samples (n=2) were artificially inoculated with PEDV and MgV. Then
106 pH was adjusted to 6.0 and Al(OH)₃ precipitate formed by adding 1 part 0.9N AlCl₃
107 (Acros organics, Geel, Belgium) solution to 100 parts of sample. The pH was readjusted
108 to 6.0 and sample mixed using an orbital shaker at 150 rpm for 15 min at room
109 temperature. Then, viruses were concentrated by centrifugation at 1,700 × g for 20 min.
110 The pellet was resuspended in 10 mL of 3% beef extract pH 7.4, and samples were shaken
111 for 10 min at 150 rpm. Concentrate was recovered by centrifugation at 1,900 × g for 30
112 min and pellet resuspended in 1 mL of PBS.
113 All wastewater and effluent water samples included in this study were processed as
114 described and MgV (5 log PCRU) was spiked as process control.

115

116 **2.3. Viral extraction, detection and quantification**

117 Viral RNA was extracted from concentrates using the NucleoSpin RNA virus kit
118 (Macherey-Nagel GmbH & Co., Düren, Germany) according to the manufacturer's
119 instructions with some modifications. Briefly, 150 μ L of the concentrated sample was
120 mixed with 25 μ L of Plant RNA Isolation Aid (Thermo Fisher Scientific, Vilnius,
121 Lithuania) and 600 μ L of lysis buffer from the NucleoSpin virus kit and subjected to
122 pulse-vortexing for 1 min. Then, the homogenate was centrifuged for 5 min at 10,000 \times
123 g to remove the debris. The supernatant was subsequently processed according to the
124 manufacturer's instructions.

125 Viral RNA was detected by TaqMan real-time RT-PCR (RT-qPCR) on LightCycler 480
126 instrument (Roche Diagnostics, Germany). MgV RNA was detected by using UltraSense
127 One-Step kit (Invitrogen, SA, US) and the RT-qPCR assay as in ISO 15216-1:2017 (32,
128 33). Undiluted and ten-fold diluted MgV RNA was tested to check for RT-qPCR
129 inhibitors.

130 PEDV RNA was detected by using PrimeScript™ One Step RT-PCR Kit (Takara Bio,
131 USA) and the TaqMan RT-qPCR assay described by (34).

132 SARS-CoV-2 RNA was detected by using PrimeScript™ One Step RT-PCR Kit and the
133 RT-qPCR diagnostic panel assays validated by the US Centers for Disease Control and
134 Prevention (35). The first version of the kit with three sets of oligonucleotide primers and
135 probes was used to target three different SARS-CoV-2 regions of the nucleocapsid (N)
136 gene. The sets of primer and probes (2019-nCoV RUO Kit) as well as the positive control
137 (2019-nCoV_N_Positive Control) were provided by IDT (Integrated DNA Technologies,
138 Leuven, Belgium). Each RNA was analyzed in duplicate and every RT-qPCR assay
139 included negative (nuclease-free water) and positive controls.

140 Biobanked samples (n=4) collected in October 2019, before the first COVID-19 case was
141 documented, were used as relevant negative control to exclude false positive reactions.
142 SARS-CoV-2 RNA was quantified as genome copies (gc) by plotting the quantification
143 cycles (Ct) to an external standard curve built with 10-fold serial dilution of a quantified
144 plasmid control (IDT). MgV and PEDV RNA were quantified by plotting the Cts to an
145 external standard curve generated by serial end-point dilution method.
146 MgV recovery rates were calculated and used as quality assurance parameters according
147 to ISO 15216-1:2017 (33).

148

149 **3. Results and Discussion**

150 **3.1. Performance of the concentration method**

151 The aluminum hydroxide adsorption-precipitation method was tested by spiking influent
152 and effluent samples with MgV and PEDV. On average, MgV was recovered at ranges
153 of $10.85 \pm 2.11\%$ in influent and $6.19 \pm 1.00\%$ in effluent water. PEDV was recovered at
154 ranges of $10.90 \pm 3.54\%$ in influent and $3.29 \pm 1.58\%$ in effluent water. These results are
155 in line with the MgV recoveries reported for enteric viruses concentration in water
156 samples by the same aluminum-based method (19, 30) and higher than the 1% as the
157 quality assurance parameter indicated for bottled water into ISO 15216-1:2017 (33).

158 Similarly, MgV was successfully used as recovery control for hepatitis E virus
159 concentration from influent and effluent water samples (5-13%) by applying a
160 polyethylene glycol (PEG) precipitation method (20). A similar PEG-based protocol was
161 recently used to recover SARS-CoV-2 from wastewater, although recovery control was
162 not included in the study (23).

163 Moreover, filtration through 10 kDa Centricon[®] Plus-70 centrifugal device successfully
164 recovered SARS-CoV-2 in wastewater with recovery efficiencies of F-specific RNA

165 phages of 73% (22). However, concentration by electropositive membrane should be
166 further evaluated given a SARS-CoV recovery from wastewater of 1% (36).
167 Rigorous limits of detection should be established by spiking SARS-CoV-2 cell-culture
168 adapted strain or positive COVID-19 fecal samples in influent and effluent wastewater
169 samples to be concentrated following the aluminum hydroxide adsorption-precipitation
170 method. Nonetheless, the need of a BSL3 laboratory facility to handle SARS-CoV-2
171 represents the main limitation of this experiment.

172

173 **3.2. SARS-CoV-2 titers in wastewater and effluent water**

174 A total of 42 influent, and 18 secondary and 12 tertiary treated effluent water samples
175 were collected from 12 March to 14 April 2020 and investigated for the occurrence of
176 SARS-CoV-2 RNA. Samples were considered positive for Ct below 40 (as in Medema et
177 al., 2020 and F. Wu et al., 2020) and titrated by using the quantified plasmid control for
178 each of the RT-qPCR targets.

179 The 85.7% (36 positive samples out of 42) influent samples were tested positive for at
180 least one SARS-CoV-2 RT-qPCR target. None (0 out of 30) of the secondary and tertiary
181 effluent samples tested positive for any of the SARS-CoV-2 RT-qPCR target (Figure 2).
182 A relevant number of influent water samples (12%) showed Ct ranging between 37 and
183 40, even though lower Ct of 34-37 were observed (29%). In all samples, MgV recoveries
184 were above 1% ($10.05 \pm 14.10\%$). Detection of SARS-CoV-2 RNA in influent water has
185 been reported worldwide (22–24, 26), and only one study tested treated wastewater that
186 resulted positive (Paris) (25).

187 On average, SARS-CoV-2 RNA titers of 5.15 ± 0.25 , 5.53 ± 0.24 , and 5.49 ± 0.27 log
188 gc/L were quantified in wastewater by using N1, N2 and N3 primer/probe mixes,

189 respectively. Titer of 4 and 5 to more than 6 log gc/L have been reported in Massachusetts
190 and France, respectively (23, 25).

191 We observed discrepancies among RT-qPCR N1, N2 and N3 assays for several water
192 samples in agreement to a previous report (22). This could be due to the different
193 analytical sensitivity among the assays as well as the detection of possible false positive
194 samples by RT-qPCR N3 in low concentrated samples (37, 38). The latter possibility has
195 been solved by excluding the N3 primers/probe set from the US CDC 2019-nCoV RT-
196 qPCR diagnostic panel in its last revision (March, 30) (39). In addition, a partial inhibitory
197 effect of the matrix is not to be completely excluded despite the controls included in the
198 assays. A more sensitive estimation of SARS-CoV-2 loads in wastewater should be
199 studied by digital RT-qPCR (dRT-qPCR). dRT-qPCR could be used to quantify samples
200 with low viral loads, even though it may not be the best practical and economically
201 sustainable option for environmental surveillance.

202 Even though the SARS-CoV-2 RNA detection in wastewater is functional for WBE
203 purposes, the risk for human health associated to the water cycle is still under debate as
204 infectivity of viral particles remain to be confirmed as well as its potential fecal-oral
205 transmission.

206 In spite of the high concentration of viral RNA in specimen and the evidence of
207 gastrointestinal infection (10), infectious viruses from stools have been isolated in one
208 study (9) while another attempt resulted without success (2).

209 The potential transmission of SARS-CoV-2 via wastewater has not been proven (40, 41)
210 and it seems unlikely given the poor viral stability in environmental conditions and its
211 elevated sensitivity to disinfectants (26, 42, 43).

212

213 **3.3. Environmental surveillance**

214 Epidemiological data on COVID-19 in the Murcia Region have been retrieved from the
215 publically available repository of the “Servicio de epidemiología” of the “Consejería de
216 Salud de la Región de Murcia” (available at <http://www.murciasalud.es/principal.php>)
217 (Table 3) and plotted to the SARS-CoV-2 RNA mean loads as detected by three RT-
218 qPCR assays (Figure 2).

219 In general, RT-qPCR amplification signals have been detected in wastewaters when cases
220 were diagnosed within the municipality. Positive wastewater samples have been detected
221 with at least two out of three RT-qPCR assays in low prevalence municipalities as in
222 Murcia (96 cases, 21.18 cases per 100,000 inhabitants), Cartagena (36 cases, 16.76) and
223 Molina de Segura (12 cases, 16.69). Of note, positive wastewater samples were detected
224 12-16 days before COVID-19 cases were declared in Lorca, Cieza and Totana
225 municipalities.

226 A similar study conducted in Paris (France) demonstrated the detection of viral genome
227 before the exponential phase of the epidemic (25). However, our results indicate that
228 SARS-CoV-2 can be detected weeks before the first confirmed case. The early detection
229 of SARS-CoV-2 RNA in wastewater could have alerted about the imminent danger,
230 giving a valuable time to the managers to coordinate and implement actions to slow the
231 spread of the disease. Therefore, our outcomes support that WBE could be used as an
232 early warning tool to monitor the status and the trend of COVID-19 infection within a
233 community.

234 On the other hand, we believe that this environmental surveillance could be used as an
235 instrument to drive the right decisions to reduce the risk of lifting restrictions too early.
236 In fact, a very important question is to determine what needs to be implemented to have
237 reliable data to reduce the risk of a “second wave”. Massive population tests are the first
238 choice, but in their absence, wastewater monitorization of SARS-CoV-2 RNA can give a

239 reliable picture of the current situation. Our wastewater data do not quantitatively
240 resemble the prevalence of COVID-19 confirmed cases. To this end, a quantitative model
241 that includes and corrects all the variables affecting these wastewater surveillance data
242 would be useful for a better interpretation. For instance, not all COVID-19 positive
243 patients excrete SARS-CoV-2 RNA in faeces, and when it occurs, the titers and the
244 duration of shedding vary among individuals and across time (1, 2, 5, 7). On the other
245 hand, the real number of positive cases within the Murcia Region remains unknown
246 because of the large number of mild or asymptomatic carriers that have not been included
247 in epidemiological statistics.

248 These aspects together with environmental variables (e.g., rainfall events, temperature)
249 increase the uncertainties linked to the correlation between SARS-CoV-2 RNA detection
250 in wastewater samples and the prevalence of COVID-19 that could be explored by using
251 complex models.

252 In conclusions, wastewater surveillance and WBE may represent a complementary
253 approach to estimate the presence and even the prevalence of COVID-19 in communities.
254 This represents an effective tool that needs to be further explored in order to direct public
255 health response, especially in cases of limited capacity for clinical testing.

256

257 **Funding**

258 The study was funded by the projects 20180705 of ESAMUR, 202070E101 of CSIC and
259 “VIRIDIANA” AGL2017-82909 (AEI/FEDER, UE) of MICIU. WR is supported by
260 APOSTD/2018/150 postdoctoral fellowship of Generalitat Valenciana. EC-F is recipient
261 of a predoctoral contract from the MICINN, Call 2018. PT is holder of the RYC2018-
262 025510-I Ramón y Cajal contract from the MICIU.

263

264 **Acknowledgments**

265 The authors acknowledge the “Entidad Regional de Saneamiento y Depuración de Aguas

266 Residuales (ESAMUR)” for authorizing the sampling and Prof. Ana Carvajal (Faculty of

267 Veterinary Medicine, University of Leon, Spain) for kindly providing PEDV.

417 **Figure 1.** Maps of the sampling location. Symbols represents WWTPs and are sized
418 according to the number of equivalent inhabitants.

419

420 **Table 1.** Operating characteristics of WWTPs.

	Population		Capacity (m ³ /a)		Reclamation processes	Reuse
	Connected	Equivalent	Designed	Current		
Murcia	370,893	530,499	36,500,000	36,952,999	Activated sludge (A2O process), Disinfection, NaClO	Public domain
Cartagena	175,870	163,969	12,775,000	8,625,103	Activated sludge, Disinfection	Irrigation
Molina de Segura	67,455	150,545	9,125,000	5,699,930	Activated sludge, Decantation, Coagulation, Flocculation, Sand filtration, Disinfection, UV, NaClO	Irrigation
Lorca	73,057	101,161	7,300,000	3,366,919	Activated sludge, Coagulation, Flocculation, Sand filtration, Disinfection, UV, NaClO	Irrigation
Cieza	33,744	69,502	3,650,000	2,338,673	Activated sludge (Extended aeration), Disinfection, Coagulation, Flocculation, Sand filtration, Disinfection, UV	Irrigation
Totana	29,113	28,289	2,190,000	1,440,463	Activated sludge (Extended aeration), Disinfection, UV	Irrigation

422 **Figure 2.** Mean amplification cycles of SARS-CoV-2 RNA in influent, secondary and
 423 tertiary effluent waters in monitored WWTPs within Murcia Region (Spain).
 424 Results are reported for each of the three regions of the virus nucleocapsid (N) gene
 425 according to the first version of the Real-Time RT-PCR Diagnostic Panel by US CDC.
 426 Abbreviations: -, negative; white boxes, not tested.
