36

37 **Abstract:** The coronavirus disease 2019 (COVID-19) pandemic has posed a major  
38 challenge for protecting health care workers (HCWs) against the infection. Use of  
39 personal protective equipment (PPE) in health care workplace is recommended as a high  
40 priority. In order to investigate the relationship between PPE use and the number of  
41 COVID-19 cases among HCWs, we conducted a molecular epidemiological study among  
42 142 HCWs who were dispatched from Hefei to work in Wuhan and 284 HCWs who  
43 remained in Hefei, China; both provided care for patients with COVID-19. Nucleic acid  
44 testing and SARS-CoV-2 specific antibody (IgM, IgG, IgA) detection were performed to  
45 confirm SARS-CoV-2 infection among those HCWs. We also extracted publicly released  
46 data on daily number of COVID-19 cases among HCWs, daily number of HCWs who  
47 were dispatched to Hubei province since January 24, and daily production of PPE in  
48 China and daily demand and supply of PPE in Hubei province. Our laboratory testing  
49 confirmed that none of the 142 HCWs who were dispatched to work in Wuhan and 284  
50 HCWs who remained in Hefei were infected by SARS-CoV-2. Consistent with these  
51 findings, as of April 15, 2020, none of the 42,600 HCWs who were successively  
52 dispatched to Hubei province since January 24, 2020 was reported to have COVID-19.  
53 These HCWs were provided with adequate supply of PPE as committed by their original  
54 institutions or provinces. In contrast, during the early phase of COVID-19 epidemic in  
55 Hubei province, a substantial shortage of PPE and an increasing number of COVID-19  
56 infection among HCWs were reported. With the continuing increase in domestic  
57 production of PPE in China, the PPE supply started to meet and then exceed the demand.  
58 This coincided with a subsequent reduction in the number of reported COVID-19 cases  
59 among HCWs. In conclusion, our findings indicate that COVID-19 infection among

60 HCWs could be completely prevented. Appropriate and adequate PPE might play a  
61 crucial role in protecting HCWs against COVID-19 infection.

62

## 63 INTRODUCTION

64 Coronavirus disease 2019 (COVID-19), first reported in Wuhan, Hubei province,  
65 China in December 2019,<sup>1-3</sup> has emerged as a pandemic worldwide. It is caused by a  
66 novel coronavirus,<sup>4-6</sup> now known as the severe acute respiratory syndrome coronavirus 2  
67 (SARS-CoV-2).<sup>7</sup> As of April 18, 2020, the pandemic has affected more than 200  
68 countries and regions around the world, with a total number of confirmed cases more than  
69 2.1 million, of whom more than 139,515 people died due to COVID-19.<sup>8</sup> The United  
70 States is now the country with the largest number of reported cases, comprising about  
71 one-fifth of all reported infections.<sup>9</sup> Moreover, the global number of infected cases is  
72 rapidly increasing, posing a serious threat to global public health.<sup>10</sup>

73 As the SARS-CoV-2 spreads globally, a major challenge is ensuring successful  
74 protection of health care workers (HCWs) against COVID-19. HCWs are at high risk of  
75 COVID-19 infection because of their close contact with infected patients in a relatively  
76 closed environment. A recent report from Wuhan, China showed that 1496 local HCWs  
77 in Wuhan had confirmed COVID-19 from December 8, 2019 to March 8, 2020, with  
78 daily rate of cases in local HCWs 3 times higher than that in the general population.<sup>11</sup>  
79 Thousands of COVID-19 cases or even deaths from COVID-19 have been reported  
80 among HCWs in other emerging epicenters, such as Italy,<sup>12</sup> Spain, and the United States.

81 To protect HCWs against COVID-19 infection, use of personal protective  
82 equipment (PPE), such as masks, protective clothing, gloves, and goggles, in health care  
83 workplace has been recommended as a high priority.<sup>13</sup> PPE is not only important for  
84 HCWs who directly provide care for patients with known COVID-19, but also for HCWs  
85 in general practice because there are undiagnosed patients or even asymptomatic patients.<sup>14</sup>

86 However, limited availability or serious shortage of PPE, especially N95 masks and  
87 protective clothing, is reported worldwide.<sup>15</sup> It is imperative to understand whether and to  
88 what extent PPE use protects HCWs against COVID-19.

89 So far, COVID-19 outbreak in Wuhan and throughout China has been temporarily  
90 controlled.<sup>11</sup> During the early phase of COVID-19 outbreak, the rate of COVID-19  
91 infection among local HCWs in Wuhan rapidly increased from December 8, 2019 to  
92 January 22, 2020 and peaked through February 1, 2020,<sup>11</sup> which was accompanied by  
93 insufficient PPE supply and limited knowledge of this novel disease. In response, a series  
94 of multifaceted efforts has been implemented,<sup>11</sup> including increasing PPE production and  
95 allocating nationwide PPE supply to Hubei province. Moreover, from January 24 to  
96 March 8, 42,600 HCWs from 30 other provinces were successively dispatched to Hubei  
97 province, ensuring the adequacy of medical personnel in the epidemic area.<sup>12</sup> Because  
98 most of these HCWs were not specialized infectious disease or respiratory disease, it was  
99 very challenging to ensure protecting them against COVID-19 infection. Most of these  
100 HCWs remained in Hubei province until the outbreak of COVID-19 in Hubei province  
101 was controlled. During this period, PPE availability was largely improved, and  
102 comprehensive PPE was widely used among HCWs.

103 We conducted a molecular epidemiological study to confirm SARS-Cov-2  
104 infection status among two groups of HCWs (one group were dispatched from Hefei to  
105 work in Wuhan and the other group remained in Hefei). We analyzed publicly released  
106 nationwide and regional data to depict the secular trends in PPE availability and the  
107 number of reported COVID-19 cases among HCWs. We hypothesize that PPE use may  
108 play an important role in the prevention of COVID-19 infection among HCWs.

109 **METHODS**

110 The study protocol was approved by the Institutional Review Board at the  
111 University of Science and Technology of China (USTC).

112 **Data sources for the analyses of PPE availability and COVID-19 cases among**  
113 **HCWs in Hubei province**

114 We extracted daily number of confirmed COVID-19 cases of HCWs during the  
115 early phase of COVID-19 response in China (as of February 14, 2020) from the data of  
116 epidemiological survey of 72,314 COVID-19 cases, which were reported by Chinese  
117 Center for Disease Control and Prevention.<sup>16,17</sup> In addition, we obtained daily number of  
118 HCWs who were dispatched to work in Hubei province from January 24 to March 1,  
119 2020, according to reports of National Health Commission of the People's Republic of  
120 China (NHCPRC) and Health Commission of each of the 30 original provinces where the  
121 HCWs were dispatched from (**Supplementary Table 1**). We also obtained data about  
122 daily capacity of production of PPE (e.g., protective clothing) in China and daily demand  
123 and supply in Hubei province from websites of NHCPRC and the Health Commission of  
124 Hubei Provincial (HCHP). Data sources were listed in **Supplementary Table 2-4**.

125 **Molecular epidemiological study**

126 *Study population*

127 In this molecular epidemiological study, we included two groups of HCWs,  
128 including HCWs who were dispatched from Hefei to work in Wuhan and those who  
129 remained in Hefei. Hefei is the capital city of Anhui province, which is around 235 miles  
130 away from Wuhan. On February 13, 2020, 142 HCWs (49 males and 93 females) from  
131 Hefei were dispatched to Wuhan, then took over the designated Sixth Special Ward for

132 patients with severe conditions and worked there for 35 days. HCWs were called from  
133 multiple clinical departments, including ICU, infectious disease department, and other  
134 departments, because of the need of multidisciplinary care for COVID-19 patients with  
135 multiple organ infections and/or comorbid chronic diseases, such as hypertension,  
136 coronary heart disease, diabetes and malignant tumors. When treating COVID-19 patients,  
137 these HCWs were equipped with appropriate and adequate PPE including protective  
138 clothing, masks, gloves, goggles and face shields. After the COVID-19 in Wuhan was  
139 controlled, they returned to Hefei on March 18, 2020 and were quarantined for 14 days.  
140 Throat swab samples and blood samples were collected on March 25, 2020, which was  
141 during the quarantine period. All HCWs in this group were released from quarantine on  
142 April 1, 2020. For comparison, we also collected throat swab samples and blood samples  
143 among 284 local HCWs in Hefei who provided care for COVID-19 cases but were not  
144 dispatched to work in Wuhan.

#### 145 *Nucleic acid testing*

146 Throat swab samples were subjected to Real-Time Fluorescent RT-PCR to test for  
147 SARS-CoV-2 viral RNA. Briefly, the swabs were incubated in a water bath at 56 °C for  
148 30 minutes. The total RNAs were then extracted with magnetic beads by automatic  
149 nucleic acid extractor (Jiangsu Shuoshi) and subsequently added into the amplification  
150 tubes. RT-PCR was performed using Real-Time Fluorescent RT-PCR Kit (BGI,  
151 sensitivity: 100 copies/mL) or The DaAn Gene nCov RNA Kit (DAAN GENE,  
152 sensitivity: 500 copies/mL) on a Slan 96P Real Time PCR System (Shanghai Hongshi  
153 Medical Technology Co., Ltd).

#### 154 *SARS-CoV-2 specific antibody detection*

155 Serum SARS-CoV-2 specific antibody levels were measured with  
156 chemiluminescent kits (Kangrun Biotech) for IgA (Doc no. KR/CE-01-B10, Revision  
157 A/0), IgG (Doc no. KR/CE-02-B10, Revision A/0) and IgM (Doc no. KR/CE-03-B10,  
158 Revision A/0). Briefly, the NP or RBD viral antigens were coated to magnetic particles to  
159 catch SARS-CoV-2 specific IgA, IgM and IgG in patient sera. Then a second antibody  
160 that recognizes IgA, IgM or IgG and is conjugated with acridinium (which can react with  
161 substrates to generate a strong chemiluminescence) was added for detection of IgA, IgM  
162 and IgG, respectively. The detected chemiluminescent signal over background signal was  
163 calculated as relative light units (RLU), COI was the ratio of RLU to statistically  
164 determined cut-off (criterion). Serum samples were collected by centrifugation of whole  
165 blood in test tubes at room temperature for 15 min. Prior to testing, a denaturant solution  
166 was added to each serum to a final concentration of 1% TNBP, 1% Triton X-100. After  
167 adequate mixing by inverting, the samples were incubated at 30°C for 4 hours to  
168 completely denature any potential viruses. Such solvent/detergent (1% TNBP + 1% Triton  
169 X-100) treatment is recommended by WHO guidelines on viral inactivation and removal  
170 procedures intended to assure the viral safety of human blood plasma products.<sup>18</sup> Virus  
171 deactivated serum samples were then diluted 40 times with dilution buffer and subjected  
172 to testing at room temperature. Then RLU was measured using a fully automatic  
173 chemical luminescent immunoanalyzer, Kaeser 1000 (Kangrun Biotech, Guangzhou,  
174 China).

175 SARS-CoV-2 RBD-specific IgA, IgM and IgG antibodies were purified from a  
176 serum pool of recovering patients (published elsewhere) to be used as standards. The  
177 concentrations were determined using Bradford method (using bovine serum albumin

178 protein as a standard). These antibodies were used to make a standard curve for each  
179 antibody detection kits to quantify the absolute antibody amounts in serum.

### 180 **Statistical analysis**

181 We presented categorical variables among HCWs who were dispatched from  
182 Hefei to work in Wuhan and those who remained in Hefei as count (%). We used SPSS  
183 (version 19.0) for all the analyses.

### 184 **Role of the funding source**

185 The funder of the study had no role in study design, data collection, data analysis,  
186 data interpretation, or writing of the report. The corresponding author JPW had full  
187 access to all the data in the study and had final responsibility for the decision to submit  
188 for publication.

189

## 190 **RESULTS**

### 191 **Molecular epidemiological study of COVID-19 among HCWs**

192 We tested 142 HCWs (49 males and 93 females), including physicians and nurses  
193 from the First Affiliated Hospital of USTC, who were dispatched to Hubei to fight  
194 against the outbreak of COVID-19. Only about a quarter of these HCWs were from ICU,  
195 infectious disease, respiratory medicine, emergency, anesthesiology departments, and the  
196 majority was from other departments who had relatively less experience in dealing with  
197 infectious diseases. Surprisingly, among them, both the nucleic acid tests and serological  
198 antibody tests showed that none of these HCWs was infected with SARS-CoV-2. The test  
199 of serological antibodies included IgA, IgM and IgG, which ruled out the possibility of  
200 asymptomatic infection.

201 We also performed the nucleic acid tests and serological antibody tests on 284  
202 HCWs who remained in Hefei and did not work in Wuhan. Similarly, both the nucleic  
203 acid and serological antibody tests showed no SARS-CoV-2 infection among them  
204 **(Table 1)**.

#### 205 **Trends in PPE availability and COVID-19 cases among HCWs in Hubei province**

206 A substantial shortage of PPE was reported during the early phase of COVID-19  
207 epidemic in China. According to data reported by NHCPRC and the Ministry of Industry  
208 and Information Technology of the People's Republic of China (MIITPRC), during the  
209 period from January 23 to February 1, the daily demand of PPE was on average 100,000  
210 sets per day, while China's domestic average capacity of production was less than 10,000  
211 sets per day. During that period, PPE supply was heavily dependent on overseas imports  
212 and donations except domestic production. With the continuing increase in domestic  
213 production of PPE in China, the PPE supply started to meet and then exceed the demand.  
214 On February 7, 2020, Hubei province needed about 59,400 sets of PPE per day, while  
215 China's daily production capacity reached 48,500 sets. Together with overseas imports  
216 and donations, the demand and supply were tightly balanced at that time. After March 6,  
217 2020, daily production of PPE in China reached 500,000 sets, exceeding the daily  
218 demand **(Figure 1)**.

219 The number of confirmed COVID-19 infections among HCWs in China increased  
220 since the outbreak in December 2019, peaked on January 28, 2020, and then dropped  
221 gradually thereafter **(Figure 2)**. As a strategy to provide sufficient HCWs to deal with the  
222 drastically increased number of COVID-19 patients and to compensate the reduced  
223 number of available HCWs in Hubei province due to COVID-19 infection and quarantine,

224 42,600 HCWs from other provinces were successively dispatched to work in major  
225 hospitals in Hubei province since January 24, 2020. As of April 16, 2020, none of the  
226 42,600 HCWs was reported to have COVID-19 infection (**Figure 3**).

227

## 228 **DISCUSSION**

229 This molecular epidemiological study of two groups of HCWs confirmed that  
230 HCWs who were dispatched to work in Wuhan and those who remained in Hefei were  
231 not infected by SARS-CoV-2. The antibody testing including IgA, IgM and IgG was able  
232 to exclude any asymptomatic infections in the HCWs if any. Therefore, our findings  
233 supported the report about zero infection of COVID-19 among 42,600 HCWs who were  
234 successively dispatched to Hubei province to fight against COVID-19.<sup>19</sup> Many HCWs  
235 worked in Hubei province for two months with high risk of contracting the virus. Along  
236 with more than 80,000 local HCWs in Hubei province, these HCWs had cured 55,987  
237 COVID-19 patients in Hubei province. However, they remained free of COVID-19  
238 infection.

239 Our analysis of national and regional PPE availability suggested a potential  
240 association between PPE use and reduction in COVID-19 infections among HCWs.  
241 During the early phase of the epidemic in Hubei province, data from both NHCPRC and  
242 MIITPRC showed an extreme shortage of the PPE and other medical supplies for HCWs  
243 in Hubei province. For example, the daily supply of protective clothing only met for less  
244 than 10% of the demand at that time. During that period, hundreds of HCWs were  
245 infected with COVID-19 in Hubei province, and the number of COVID-19 cases among  
246 HCWs in Hubei province accounted for over 90% of the cases among HCWs nationwide.

247 Subsequently, with nationwide efforts to promote domestic production, the supply of PPE  
248 was gradually meeting the demand since early February 2020, which is in parallel with  
249 the decrease in the number of COVID-19 cases among HCWs. Since early March, the  
250 emergency state has been reversed to a surplus status. Coincidentally, the rapid increase of  
251 COVID-19 infection among local HCWs in Wuhan from December 8, 2019 to January  
252 22, 2020, peaked from January 23 to February 1, 2020, and then decreased from February  
253 2 to March 8, 2020.<sup>11</sup>

254 An important measure to protect the HCWs to be dispatched to Hubei province  
255 was adequate supply of PPE, as committed and provided by their original institutions or  
256 provinces. This was crucial because of the limited supply of PPE in Hubei province at  
257 that time. For example, Jiangsu province, which dispatched the largest number of HCWs  
258 (n=2,802) to Hubei province, sent 545,800 pieces of medical supplies including 516,000  
259 pieces of PPE, to Hubei province by February 22, 2020. Similar measures to ensure PPE  
260 supply were taken from other provinces which dispatched HCWs to Hubei province. The  
261 adequate supply and use of PPE were likely to play an important role in the successful  
262 protection of all HCWs dispatched to Hubei province with no COVID-19 infection  
263 among them.

264 It is noteworthy that not all the HCWs that were dispatched to Hubei province had  
265 expertise in infectious disease or respiratory disease. In the present study, the majority of  
266 HCWs that were dispatched from Hefei to work in Wuhan were from departments other  
267 than ICU, infectious diseases, or respiratory diseases. Although these HCWs were  
268 provided adequate PPE, they had limited experience dealing with infectious agents in  
269 their previous clinical work. If not protected, exposure to symptomatic or asymptomatic

270 patients of COVID-19 could cause infections among some HCWs. However, even among  
271 them, no one was infected with SARS-CoV-2, which further strengthened the importance  
272 of adequate PPE supply and use for HCWs.

273 Our findings about a potential relation between PPE use and successful protection  
274 against COVID-19 among HCWs were in line with available, although still limited,  
275 evidence. SARS-CoV-2 is primarily transmitted through droplets and in some  
276 circumstances, through aerosols.<sup>9,20</sup> Recently, a study found that surgical masks  
277 significantly reduced detection of coronavirus RNA in aerosols, with a trend toward  
278 reduced detection of coronavirus RNA in respiratory droplets, indicating that surgical  
279 masks could prevent transmission of human coronaviruses from symptomatic  
280 individuals.<sup>21</sup> Nosocomial transmission of SARS-CoV-2 has been reported among  
281 hospitalized patients and HCWs.<sup>22</sup> A recent study showed extensive environmental  
282 contamination by a patient with SARS-CoV-2 through respiratory droplets and fecal  
283 shedding, which suggests the environment as a potential medium of transmission.<sup>23</sup>  
284 Therefore, in order to block the various spreading routes of the virus, application of  
285 comprehensive PPE including masks, protective clothing, gloves, goggles and face shield,  
286 etc. is warranted to provide effective protection for HCWs.

287 This study has important clinical implications. Although HCWs often accept  
288 increased risk of infection, as part of their chosen profession, any possible effort must be  
289 taken to minimize their risk of COVID-19 infection. The first wave of COVID-19  
290 outbreak in Wuhan and throughout China has been successfully controlled, with the  
291 lockdown of Wuhan and a series of multifaceted interventions.<sup>11</sup> However, emerging  
292 epicenters around the world, such as Italy,<sup>24</sup> Spain, and the United States,<sup>9</sup> are currently

293 experiencing similar epidemiologic curve as what happened in January and early  
294 February in Wuhan, China. Therefore, learning experience from China may help inform  
295 policy making in other countries and regions. The laboratory-confirmed zero infection of  
296 COVID-19 in this study offers a promising message to the HCWs that their risk might be  
297 greatly reduced or even eliminated with appropriate and adequate PPE use.

298         This study has several limitations. First, like other observational studies, the  
299 present study could not establish causality between PPE use and the successful  
300 prevention of COVID-19 infection among HCWs. Due to ethical consideration, it is  
301 impossible to conduct experimental studies to compare infections between HCWs  
302 wearing and not wearing PPE. Only historical data of different periods could be used to  
303 test our hypothesis. Second, PPE consists of various items such as protective clothing,  
304 N95 masks, surgical masks, gloves, and goggles, etc. This study only presents the data of  
305 medical protective clothing because protective clothing is representative of PPE  
306 production and supply in China. Third, we were not able to test all the 42,600 HCWs who  
307 were dispatched to Hubei province. Finally, we did not have information about the HCWs'  
308 personal prevention awareness and adherence at individual level which may also  
309 influence the infection among HCWs.

310         In conclusion, our laboratory-confirmed findings of zero infection indicate that  
311 COVID-19 infection among HCWs could be completely prevented. Appropriate and  
312 adequate PPE might play a crucial role in protecting HCWs against COVID-19 infection.  
313 Therefore, it is critical and urgent to ensure sufficient PPE in health care workplace to  
314 protect HCWs from COVID-19 infection while they are fighting against the pandemic.

315 **Contributors:** WW, YZM, CMY, WB, and JPW designed the study. WW, YZM, and  
316 CMY collected the data. WW and YZM analysed the data. WW, YZM, CMY, WB, and  
317 JPW interpreted the data. WW wrote the first draft. WW, YZM, and CMY contributed  
318 equally to this work. All authors contributed to the final draft.
