**Objective**

To evaluate the preference and satisfaction in the Chinese Parkinson's disease (PD) patients treated with deep brain stimulation (DBS).

**Background**

DBS is a widely used therapy for PD. There is now a choice between fixed-life implantable pulse generators (IPGs) and rechargeable IPGs, each having their advantages and disadvantages.

**Methods**

Two hundred and twenty PD patients treated with DBS completed a self-designed questionnaire to assess long-term satisfaction and experience with the type of battery they had chosen, and the key factors affecting their choices. The survey was performed online and double-checked for completeness and accuracy.

**Results**

The median value of follow-up length was 18 months. The most popular way for patients to learn about DBS surgery was through media (79/220, 35.9%), including the Internet and television programs. 87.3% of the DBS used rechargeable IPGs (r-IPG). The choice between rechargeable and non-rechargeable IPGs was significantly associated with the patient's affordability ($\chi^2_{(1)}$ = 19.13, p < 0.001). Interestingly, the feature of remote programming significantly affected patients' choices between domestic and imported brands ($\chi^2_{(1)}$ = 16.81, p < 0.001). 87.7% of the patients were satisfied with the stimulating effects as well as the implanted device. 40.6% of the patients with r-IPGs felt confident handling their devices within one week after discharge. More than half of the patients checked their batteries every week. The

mean interval for battery recharge was 4.3 days. 57.8% of the patients spent around

one-hour recharging, and 71.4% of them recharged the battery independently.

**Conclusion**

Most patients were satisfied with their choices of IPGs.  The patients' financial status

and remote programming function were the two most critical factors in their decision.

The skill of using rechargeable IPG was easy to master by most patients.

**Introduction**

Deep brain stimulation (DBS) is a well-established neurosurgical treatment for advanced Parkinson's disease (PD), which achieves its effects by continuous electrical current delivery to the target brain area. The power comes from an implantable pulse generator (IPG), which was initially designed to be non-rechargeable. Depending on the diagnosis and parameter settings, these fixed-life batteries had to be replaced three to five years after implantation. As the continuous stimulation calls for high energy consumption, battery depletion is the most common reason for further surgery in DBS patients. [1,2] Despite the battery replacement is a minor surgical procedure compared with the primary operation, several problematic issues such as infection risk and wound healing may occur after several IPG replacements. [3] Rechargeable batteries were introduced in 2008. Compared to fixed-life ones, rechargeable batteries offer several advantages, including smaller profile but longer battery life, requiring fewer battery replacement surgeries, and fewer battery exhausted–related problems (e.g., injuries caused by worsening of symptoms). [4] Research on the utility of rechargeable batteries for DBS have demonstrated adequate tolerability, a high patient satisfaction rate, and a favorable cost-effectiveness. However, patients are required to check the battery status and regularly recharge by using a handheld device. The frequency and duration of the recharge procedure depend on the power consumption of each patient. Although it is not difficult to perform, the recharge procedure can be challenging for PD patients as most of them are the elderly with various levels of cognitive deficits. [5]

In addition to battery options, rapid technological development in the last decade has made neurologists and neurosurgeons—face the challenge of selecting an ideal

individualized DBS system based on multiple variables such as lead geometry and

different programming platforms.[6] Factors including DBS target, the amount of

current needed, patient's overall health condition and their ability to deal with

interactive devices and recharging, social support network, and personal financial

status are of prime importance in delivering individualized therapy to patients.

Another critical area that has not been fully explored is the influence of patient's

individual preferences and lifestyle concerns on the choice of the DBS device. The

patient's decision on DBS battery choice and the influencing factors of the decision

have only been investigated in a few studies in Europe. [5,7–9]

Neuromodulation with implantable devices is one of the most technologically driven

disciplines within neurosurgery. In recent years, there has been a considerable

expansion in choices of available DBS hardware allowing for more personalized

therapies, maximizing the benefits and acceptability, whilst minimizing the risks. At

the same time, DBS specialists also face the challenge of selecting among a mass of

options to choose the most appropriate device for each patient. Understanding why

and how patients make their choices is critical not only to improve patient

acceptability and satisfaction of the therapy but also to innovate the next generation

devices. In China, three DBS manufacturers (Medtronic, PINS and SceneRay) are

currently offering non-rechargeable (nr-IPG) and rechargeable IPGs (r-IPG) from

1998 and 2013, 2013 and 2014, 2016 and 2019, respectively (Supplementary Figure

1). In this article, we sought to report patients' satisfaction and preferences for the

type of IPGs they chose.

**Method**

Participants

Patients diagnosed with idiopathic PD who had undergone DBS surgery in the

Department of Functional Neurosurgery in Ruijin Hospital Affiliated to Shanghai Jiao

Tong University School of Medicine were invited to participate in this survey. During

routine clinical practice, our patients were offered a choice of r-IPG or nr-IPG, as well

as of international or domestic brand, after a comprehensive and detailed explanation

of each option. Patients implanted with either nr-IPG or r-IPG were included in this

study. Totally 768 patients with PD who had received DBS surgeries in our center

were contacted for this study.

Questionnaire

An internet-based questionnaire (powered by www.wjx.cn) was developed and was

distributed via an online chat software Wechat. The questions comprised of various

aspects of the DBS devices that the patients had chosen, including

(but not limited to) patients' demographics, factors that impacted patients' choices,

patients' satisfaction about their choices and DBS surgery. In particular, several

questions were designed specifically for patients with an r-IPG device: the feasibility

and reliability of the battery recharge, the interval and duration of the recharge, and

the convenience of post-operative management of r-IPG. All patients provided their

consent for data collection and analysis at the beginning of the questionnaire before

study participation. This study was approved by Ruijin Ethical Committee.

Statistical analysis

Data were analyzed with the SPSS software (Version 23.0. Amonk, NY: IBM Corp.).

Continuous variables were expressed as Mean ± SD or median value with

interquartile range (IQR). Categorical variables were presented as frequencies (%).

We used Fisher's exact test to assess the relationship between patient's affordability

and the choice of r-IPG versus nr-IPG. We used Pearson's or Yates' continuity

corrected Chi-square test to evaluate the influencing factors for patients' choices of

international versus domestic manufacturers in r-IPG group, and to compare the

satisfaction rate between patients with r-IPG and nr-IPG. A p-value < 0.05 was

considered significant.

**Results**

Demographic data

220 patients (135 men and 85 women) with PD completed the survey and were

available for analysis. The response rate was 28.6% (220/768). Among them, 192

(87.3%) patients were implanted with r-IPGs and 28 (12.7%) patients with nr-IPGs.

142 (64.5%) patients had chosen a device from the international manufacturer (i.e.,

Medtronic) and 78 (35.5%) patients had chosen a device from domestic manufacturers

(i.e., PINS or SceneRay). Overall, the mean age was 62.8 ± 9.8 years. The median

value of the follow-up length was 18 (IQR: 8–36) months. Demographic data was

listed in Table 1.

Source of DBS information

The web and television media and doctor's referrals served as two important tunnels

for PD patients to know DBS before seeking surgery [36.1% (79/219) and 35.6%

(78/219), respectively]. The remaining quarter of the patients (25.5%, 56/219) came

to our center learned the information about DBS by word of mouth from other

patients (Table 2).

Influencing factors for patients' choices of rechargeable versus non-rechargeable

battery

As illustrated in Figure 1, approximately half of the patients (51.6%, 99/192) who had

chosen r-IPGs had a budget between 200 to 300 thousands RMB, while 53.6% (15/28)

of patients with nr-IPGs only had a budget between 100 to 200 thousands RMB. The

choice of r-IPG versus nr-IPG was significantly associated with the patient's

affordability ($p = 0.0001$). Concretely, the percentage of patients reporting 'concern' or

'serious concern' about economic issues was higher in the nr-IPG group (82.1%, 23/28)

than that in the r-IPG group (60.9%, 117/192) (Figure 2D). Interestingly, the need for

further surgeries to replace the battery, as well as the need for recharging the battery,

was considered a concern or a serious concern by 82.1% (23/28) and by 64.3% (18/28)

of the patients with nr-IPGs, respectively, also higher than r-IPG group (72.9%

(140/192) and 47.9% (92/192), respectively) (Figure 2B–2C). There was 46.4%

(13/28) of the patients with nr-IPGs and 51.6% (99/192) of the patients with r-IPGs

reported 'concern' or 'serious concern' about the size of the battery (Figure 2A).

Influencing factors for r-IPG patients' choices between international and domestic

manufacturers

Among 192 patients with r-IPGs, 136 (70.8%) patients had chosen a device from the

international manufacturer (i.e., Medtronic), and 56 (29.2%) had chosen a device from

the domestic manufacturer (i.e., PINS or SceneRay). The patient's economic issue, the

international reputation of the product, as well as the product feature of remote

programming significantly affected r-IPG patients' choices between international and

domestic manufacturers (p = 6.28E-7, 5.40E-11, and 3.68E-7, respectively) (Figure

3A–3C). Not surprisingly, the patient's choice was not influenced by clinicians (p =

0.202) (Figure 3D).

Satisfaction

The majority of the patients (87.7%, 193/220) were satisfied with stimulating effects

as well as the implanted device. 10% (22/220) of them claimed that their expectation

had not been met after the surgery. The satisfaction rate among patients with r-IPGs

(88.0% 169/192) showed no statistical significance compared with those with nr-IPGs

(85.7%, 24/28) (p = 0.969) (Table 3). Also, no statistical significance was observed

for the satisfaction rate between international and domestic manufacturers in patients

with r-IPGs (p = 0.729). 92.7% (178/192) of the patients with r-IPGs and 92.9%

(26/28) with nr-IPGs would choose the same type of device when completing the

questionnaire.

Recharging process

The majority of the r-IPG patients (71.4%, 137/192) were capable of battery recharge

independently. The remaining patients (28.6%, 55/192), however, needed partners to

check and recharge the battery. Most of the patients with r-IPGs and their partners

(92.7%, 178/192) felt confident of handling their device; 43.8% (78/178) of them

reported the same confidence within one week after discharge from hospital. More

than half of the patients (64.1%, 123/192) checked the battery every week, and most r-

IPG patients (92.2%, 177/192) preferred recharging when the battery level was over

50%. The mean interval for battery recharge was 4.3 days. More than half of the

patients (57.8%, 111/192) spent around 1-hour recharging. Notably, 8.3% (16/192) of

the r-IPG patients reported at least one episode of recharge failure at some point, and

more than half of them (68.9%, 11/16) failed to perform troubleshooting (Table 4).

Life with an r-IPG

During the routine recharging process, most of the r-IPG patients (92.7%, 178/192)

preferred to sit or lie down to moving around. Only 26.6% (51/192) of the r-IPG

patients reported at least one travel history after implantation, 78.4% (40/51) of whom

recharged during their vacation. 11.5% (22/192) of the r-IPG patients continued their

professional occupation after the surgery, but only one patient had recharged the IPG

at work (Table 5).

**Discussion**

To the best of our knowledge, our cohort is the largest one by far including all three

DBS manufacturers in China and reporting the preference and satisfaction of fixed life

versus rechargeable battery in PD patients. This study presented Chinese patients'

views independent of clinical influences and revealed that most patients, around 80%,

opted for the rechargeable batteries. A significant factor contributing to this choice

was related to economic status. Nevertheless, it is the effect of surgery other than the

product being the main factor that determines patient satisfaction. The remote

programming feature significantly affected patients' choice of products, which is now

only available in Chinese domestic brands. The majority of the patients with r-IPG

felt confident of mastering the recharging process within a short time after discharge.

We did not observe a difference regarding recharging patterns for three manufacturers.

Patients mostly preferred to check and recharge the battery about once a week. The

amount of time that needs to be invested by the patient to handle and recharge the IPG

is around one hour. Our cohort showed that patients were able to continue their jobs

and to travel with r-IPGs, but only a few of our patients recharged their IPGs during

work or traveling.

While greater age, as well as more advanced functional impairment, may be

considered as barriers against r-IPG utilization, neither age nor education level had a

significant impact on the understanding and performance of the recharging process in

the current study. Even if there exists a difficulty, patients can seek help from

caregivers, as approximately 30% of r-IPG patients did in our study. Interestingly,

there were several patients checked their batteries every one year or more, meaning

that they recharged the IPG frequently but they did not check the IPG status as much.

Although it was not reported in these participants, we had patients who failed to get

timely recharge. Restarting power depleted IPGs needs continuous charging for more

than 5 hours. In most cases, power depletion did not cause irreversible consequences,

but one patient got aspiration pneumonia during the power-off period.

Inability to recharge the IPG could be annoying and might have serious adverse

consequences. In our study, most cases' problems were caused by malfunctioning

power banks that needed to be replaced. One patient reported that the device was shut

down unexpectedly without the patient's awareness, and the program controller was

used to restart the IPG. Another case involved an elderly patient, whose new caregiver

failed to recharge the IPG when the original caregiver was replaced at the nursing

home.

The research concerns patient's satisfaction have been reported before. Timmermann

et al.[9] described a small prospective patient satisfaction cohort (N = 21) during a 3-

month follow-up. Jakobs et al.[5] reported another small retrospective cohort (N = 35)

with a more extensive follow-up duration (mean value of 21.2 months). Their work

together indicated that there was no significant association between the satisfaction

rate and the number of training sessions. These two studies had limited subjects which

included the patients with PD, dystonia, and essential tremor together into the analysis.

Similarly, Jakobs et al. also pointed out that the majority of patients who claimed a

lack of confidence after the training program had only participated in only one single

session. They, therefore, proposed at least two training sessions for patients. In our

study, 178 (92.7%) patients felt confident of using their IPG, and such a high rate of

satisfaction is probably because our patients and their caregivers are encouraged to

participate in two training sessions: one before discharge and one at one week after

discharge. Waln and Jimenez-Shahed et al.[10] reported patient satisfaction in a series of

31 patients of which 12 received r-IPGs as their initial implants. Interestingly, these

patients were more satisfied with their IPGs compared with patients who previously

had an nr-IPG implanted. In our study, we didn't explore the satisfaction rates

between multiple products but found the therapy efficacy was the dominating factor

of patients' general satisfaction.

Our results demonstrated that patient's affordability had a significant impact on the

choice of r-IPG versus nr-IPG in Chinese PD patients. Rizzi et al. estimated that more

than 223,000 EUR could be saved over nearly 8 years in 149 patients when they were

all implanted with r-IPG instead of nr-IPG[11]. However, reimbursement policies largely

differ across countries and cities. As DBS electrodes and IPG are now only partly

reimbursed by insurance in China, DBS therapy remains to be a substantial financial

burden for many cases. The role of insurance policies, as well as other factors like the

longevity of individual life expectancy, should be elucidated in the further cost-

effective investigation.

We recognize some limitations in this study. First, this study was undertaken in a

single institution, so there might be inherent biases. Second, as a cross-sectional study,

we are not able to identify how the patient's satisfaction developed over time as the

disease progresses. Third, the follow-up duration of the current study is not sufficient

to evaluate potential issues arising when r-IPGs are near the end of the recommended

run-time.

In conclusion, we found most patients were satisfied with their choices of IPG. The

patients' financial status and the product feature of remote programming were the two

most critical factors in their decision. The skill of using rechargeable IPG was easy to

be mastered by most patients.
