2 M.C. Nielsen has received research grants from Doctor Sofus Carl Emil Friis and Wife Olga
3 Doris Friis' grant, the Frimodt Heineke Foundation, the Harboe Foundation, Thora and Viggo
4 Groves' memorial trust, and reagent for the cell study was partly covered by Central Denmark
5 Region.

6 A. Etzerodt received research support from the Novo Nordisk foundation (NNF).

7 J. H. Graversen is part of the management of Deliver Pharma and receives support from the
8 Danish National Research Foundation and the NNF.

9 D. Berg reports advisory board service for Biogen, BIAL, Lundbeck, UCB Pharma GmbH;
10 honoraria from AbbVie, Biogen, BIAL, Lundbeck, UCB Pharma GmbH Zambon, Desitin; and
11 grants from Michael J. Fox Foundation (MJFF), Janssen Pharmaceutica N.V., German
12 Parkinson's Disease Association (dPV), BMWi, BMBF, Parkinson Fonds Deutschland
13 gGmbH, UCB Pharma GmbH, TEVA Pharma GmbH, EU, Novartis Pharma GmbH, Lundbeck
14 Foundation (LF), Damp foundation.

15 H.J. Møller received research support from the Danish Innovation Fund and the Danish Central
16 Region.

17 W. Maetzler is a co-chair of the MDS Technology Task Force and receives or received funding
18 from the EU, the MJFF, Robert Bosch Foundation, Neuroalliance, Lundbeck, and Janssen, and
19 holds part of a patent for assessing dyskinesias (German patent office, 102015220741.2). He
20 received speaker honoraria from GlaxoSmithKline, AbbVie, Bayer, UCB, Licher MT, and
21 Rölke Pharma, and was invited to Advisory Boards of Market Access & Pricing Strategy
22 GmbH, AbbVie, Roche, and Biogen.

23 A. Panhelainen received research support from the Cure Parkinson's Trust.

24 K. Brockmann has received a research grant from the University of Tuebingen (Clinician
25 Scientist), the dPV, the MJFF, and the German Centre for Neurodegenerative Diseases
26 (DZNE, MIGAP); travel grants from the Movement Disorders Society, and speaker honoraria
27 from Abbvie, Lundbeck, UCB, and Zambon.

28 M. Romero-Ramos serves on the editorial board of Brain Research, and receives research
29 support from NNF, Aarhus University Research Foundation, the Danish Medical Research
30 Council, the Danish Parkinson Foundation, Desiree and Niels Ydes Foundation, and the MJFF.

31 SKN, SAF, KS, DH, and CS report no disclosures.

32 **Funding Support**

33 Funding support for the research covered by this article was provided by the Michael J. Fox
34 Foundation (MRR), the Bjarne Saxhof Fund administered through the Danish Parkinson's
35 Foundation (MRR), the Aarhus University Research Foundation, AU IDEAS center
36 NEURODIN (MRR), and the Novo Nordisk Foundation (DEO, NNF17OC0028806). SAF is
37 funded by a PhD fellowship from the PhD School at the Health Faculty, Aarhus University.
38 The authors declare no conflict of interest.

1 **ABSTRACT:**

2

3 **Background:** Parkinson's disease (PD) is a neurodegenerative disorder with a significant
4 immune component, as demonstrated by changes in immune biomarkers in patients' biofluids.
5 However, which specific cells are responsible for those changes is unclear since most immune
6 biomarkers can be produced by various cell types.

7

8 **Objectives and methods:** To explore monocyte involvement in PD, we investigated the
9 monocyte-specific biomarker sCD163, the soluble form of the receptor CD163, in cerebrospinal
10 fluid (CSF) and serum in two experiments, and compared it with other biomarkers and clinical
11 data. Potential connections between CD163 and alpha-synuclein were studied *in vitro*.

12

13 **Results:** CSF-sCD163 increased in late-stage PD and correlated with the PD biomarkers alpha-
14 synuclein, Tau, and phosphorylated Tau, while it inversely correlated with the patients'
15 cognitive scores, supporting monocyte involvement in neurodegeneration and cognition in PD.
16 Serum-sCD163 only increased in female patients, suggesting a sex-distinctive monocyte
17 response. CSF-sCD163 also correlated with molecules associated with adaptive and innate
18 immune system activation and with immune cell recruitment to the brain. Serum-sCD163
19 correlated with pro-inflammatory cytokines and acute phase proteins, suggesting a relation to
20 chronic systemic inflammation. Our *in vitro* study showed that alpha-synuclein activates
21 macrophages and induces shedding of sCD163, which in turn enhances alpha-synuclein uptake
22 by myeloid cells, potentially participating in its clearance.

23

24 **Conclusion:** Our data present sCD163 as a potential cognition-related biomarker in PD and
25 suggest a role for monocytes both in peripheral and brain immune responses. This may be
26 directly related to alpha-synuclein's pro-inflammatory capacity but could also have
27 consequences for alpha-synuclein processing.

1 INTRODUCTION

2
3 Parkinson's disease (PD) is characterized by intraneuronal aggregations of alpha-synuclein (α -
4 syn) and dopaminergic neuronal death in the midbrain. PD also involves early and chronic
5 immune activation¹ where α -syn act as a damage-associated molecular pattern, initiating
6 inflammation and promoting disease². The immune response involves microglia in the brain
7 and blood immune cells such as monocytes/macrophages and lymphocytes. In PD patients, the
8 monocytic population shows increased proliferative and phagocytic capacity, abnormal
9 response to immune stimuli^{3, 4}, and an altered transcriptome⁵. PD-derived T cells show a bias
10 towards pro-inflammatory Th1/Th17 phenotypes^{6, 7}. Accordingly, the PD immune response
11 involves both innate and adaptive immune components. These peripheral alterations will affect
12 the central nervous system (CNS) since T cells and monocytes infiltrate the brain in PD patients
13 and models⁸⁻¹⁰. This results in changes in cytokines and chemokines in patients' serum and
14 cerebrospinal fluid (CSF). A recent meta-analysis reports increased IL-1 β , TNF- α , IL-6, and
15 IL-10 in PD patients' blood, whereas in CSF, IL-1 β , IL-6, TGF- β 1, and CRP are elevated¹¹.
16 These biomarkers correlate with PD symptomatology¹, further supporting their disease
17 relevance.

18
19 These PD-related immune biomarkers can be produced by multiple cell types¹² and cannot truly
20 reveal the unique intervention of each cell population involved in the PD immune response.
21 Conversely, this is not the case with soluble CD163 (sCD163), a well-characterized protein
22 produced exclusively by the monocyte cell lineage, but not by lymphocytes, neurons^{13, 14}, or
23 microglia, as confirmed recently by single-cell RNA analysis¹⁵⁻¹⁷. In the brain, CD163 is
24 expressed only by non-microglia CNS myeloid cells, such as meningeal and perivascular
25 macrophages¹⁷⁻¹⁹. sCD163 is constitutively produced in serum and CSF²⁰ upon immune signals,
26 through mechanisms similar to that releasing TNF- α during inflammatory processes^{21, 22}.
27 Therefore, increased sCD163 levels in biofluids relate to macrophage activation and correlate
28 with the degree of inflammation¹⁴. In the present study, we analyze sCD163 levels in serum
29 and CSF from patients with early and late PD to evaluate monocytic activation in different PD
30 stages.

MATERIALS AND METHODS:

Study participants

PD patients were recruited from the outpatient clinic and/or ward for PD, University Hospital of Tuebingen, Germany. Healthy controls (HCs) were assessed as having no neurodegenerative disease. All participants were examined by a neurologist specialized in movement disorders. A PD diagnosis was made according to the UK Brain Bank Society Criteria²³. Serum and CSF were collected and stored at the Neuro-Biobank, University of Tuebingen and sent for experimental work at Aarhus University, Denmark (see supplement). The study was approved by the local ethics committee (480/2015BO2), with all participants providing informed consent. This cross-sectional study included serum and CSF from idiopathic PD (early [$<5y$] & late [$\geq 5y$ from diagnosis]) patients and HC (**Suppl.Fig.1**). Samples were received and analyzed in two separate experiments with a two-year separation: *Exp#1*: 109 PD patients and 44 HCs (**Suppl.Table1**), and *Exp#2*: 106 PD patients and 16 HCs (**Suppl.Table2**). Twenty-eight individuals from *Exp#1* were also part of *Exp#2*; however, other aliquots were used. Furthermore, 26 additional serum HC samples remaining from *Exp#1* were included in the 40-plex mesoscale analysis in *Exp#2* (**Suppl.Table3**).

Biomarkers measurements

sCD163 was measured in serum and CSF using an in-house ELISA^{3, 24}. ELISA was used to measure CSF levels of total human Tau (h-Tau), phosphorylated Threonine 181-Tau (p-Tau), Abeta₁₋₄₂ (Abeta42) (all by Innostest), and total α -syn (Analytica Jena Roboscreen GmbH). MSD MULTI-SPOT Assay System (Mesoscale) was used to measure 40 different molecules in serum and CSF (see supplement).

α -Synuclein and sCD163 association

Evaluation of sCD163- α -syn binding was studied using Microscale Thermophoresis (MST). Monocyte-derived macrophages (MDMs) from isolated and matured human monocytes²⁵ were stimulated with 100nM, 1 μ M, or 5 μ M monomeric or fibrillar α -syn for 6 or 24 hours, followed by sCD163-ELISA measurement in supernatants. Differentiated THP-1 macrophage-like cells or BV-2 murine microglia cells were used to study ¹²⁵I- α -syn fibril uptake (50 ng/ml) alone or with sCD163 (5 μ g/ml) as a co-treatment or pre-treatment. Full-length (domain 1-9) or truncated (domain 1-5) sCD163 were used, and when stated, LPS was removed from sCD163 preparations as described²⁶ (see supplement).

1 **Statistical analyses**

2 GraphPad Prism V7, JMP 14, and STATA v15 IC were used for statistical analyses where
3 normality was first informed (see supplement).

4 **RESULTS**

5 6 **sCD163 as a biomarker related to cognition (Exp#1)**

7 First, we investigated any PD-related changes in sCD163 in Exp#1: biobank samples from 109
8 PD patients and 44 HCs (**Suppl.Fig.1; Suppl.Table1**). CSF-sCD163 was elevated in late PD
9 (**Fig.1A**), with no sex discrepancies. Serum-sCD163 levels were influenced by sex and
10 treatment (two-way ANOVA [F(7, 140)=2.86, p=0.008], sex effect p=0.039, treatment effect
11 p=0.017). Therefore, we separated the data by sex, and to eliminate the treatment variable, we
12 analyzed only treated patients. We found elevated serum-sCD163 levels in females with late
13 PD (vs. early), but not in males (**Fig.1B**). To confirm that changes in CSF-sCD163 were not a
14 simple leakage from serum, we calculated the amount of intrathecally produced and serum-
15 derived sCD163 using the ratio of albumin CSF/serum as reference (when available)²⁷. We
16 found no difference in the amount of CSF-sCD163 of serum origin (late PD 0.0132±0.001,
17 early PD 0.0139±0.001). On the other hand, intrathecally produced sCD163 was higher in late
18 PD (0.0739±0.037) than in early PD (0.0601±0.019, p=0.03), confirming elevated cerebral
19 CD163 shedding.

20 Interestingly, for PD patients, CSF-sCD163 correlated positively with well-characterized
21 neurodegenerative CSF markers (α -syn, h-Tau, and p-Tau), even after compensating for age
22 and disease duration (**Fig.1C-E, Suppl.Table4**). sCD163 also correlated with h-Tau (Spearman
23 $r=0.477$ p<0.01) and p-Tau ($r=0.36$ p<0.05) in HC. Since these biomarkers have been related
24 to PD symptomatology, we examined putative correlations between sCD163 and patients'
25 clinical scores. Remarkably, CSF-sCD163 was negatively correlated with the cognitive scores
26 MoCA and MMSE in the PD patients (**Fig.1F-H**). Serum-sCD163 also correlated positively
27 with neuronal CSF markers (**Fig.1I-K**), even after compensation for covariance
28 (**Suppl.Table4**). However, serum-sCD163 did not correlate with cognitive scores. Neither
29 serum- nor CSF-sCD163 correlated with other clinical parameters (UPDRS-III or LEDD) after
30 compensating for co-variables (not shown).

1
2 **Confirmation of sCD163 as a biomarker in PD (Exp#2)**
3 We aimed to confirm these findings in a second independent measurement with samples from
4 additional individuals in the same biobank (Exp#2) with a 2-year time gap between experiments
5 (**Suppl.Fig.1, Suppl.Table2**). Indeed, we corroborated an increase in CSF-sCD163 in late PD
6 in Exp#2 (**Fig.2A**). Again, the estimated amount of sCD163 in CSF with serum origin was
7 similar across groups (late PD 0.011 ± 0.002 , early PD 0.014 ± 0.002 , HCs 0.009 ± 0.002), while
8 the intrathecally produced sCD163 increased in late PD (0.109 ± 0.047) vs. early PD
9 (0.071 ± 0.018 , $p=0.004$) and vs. HCs (0.074 ± 0.023 $p=0.02$). This suggests increased cerebral
10 sCD163 production. We also confirmed the sex difference observed for serum-sCD163 with an
11 increase in female patients only (**Fig.2B**).

12 In agreement with observations from Exp#1, CSF-sCD163 correlated with the neuronal CSF
13 markers (α -syn, h-Tau, and p-Tau) in Exp#2 (**Fig.2C-E**). CSF-sCD163 in HC also correlated
14 with h-Tau (Spearman $r=0.61$ $p<0.05$) and p-Tau ($r=0.62$ $p<0.01$). Moreover, in Exp#2, CSF-
15 sCD163 was significantly correlated with levels of Abeta42 (**Fig.2F**). The association between
16 serum-sCD163 and CSF biomarkers showed a similar pattern, with significant correlation with
17 α -syn and p-Tau (**Fig.2J-M**).

18 Notably, this was also true for cognitive scores which decreased, while sCD163 increased in
19 PD patients (**Fig. 2G-I**). Age influenced cognition scores and sCD163; however, CSF-sCD163
20 levels remained significantly associated with cognitive decline after adjusting for age-at-visit
21 alone, or in combination with age-at-onset or disease duration for the MMSE O+C scores
22 (**Suppl.Table5**). Therefore, a 0.1mg/L increase in CSF-sCD163 corresponded to a decline of
23 ~ 3 MMSE O+C score. When adjusting for both age-at-visit and disease duration, the expected
24 MMSE decline would be ~ 1.8 (**Suppl.Table5**). This suggest that sCD163 is associated with
25 cognitive decline, even when patient age and disease duration are considered.

26
27 **Other CSF and serum biomarkers (Exp#2)**

28 To define the patients' immune profile, we measured 40 immune-related serum and CSF
29 biomarkers from Exp#2. In CSF, we observed that out of 16 reliable assays (**Suppl.Table3,**
30 **Suppl.Fig2**), seven showed PD-related changes with a $p<0.05$: VCAM-1, ICAM-1, IL-8, SAA,
31 PIGF, IL-15, and VEGF-D were increased in PD patients (**Fig.3A-K**). However, none remained
32 significant after Bonferroni correction ($\alpha=0.0031$).

1 In serum, only four markers (of 27 reliably assayed markers, **Suppl.Table3, Suppl.Fig2**)
2 showed PD-related changes with $p < 0.05$ (**Fig.3L-S**): VCAM-1 was increased in patients'
3 serum, and IL-15 and VEGF-D were both increased in late vs. early PD (**Fig.3L,R-S**), while
4 VEGF-C was decreased in all patients (**Fig.3M**). Nevertheless, none remained statistically
5 significant after Bonferroni correction ($\alpha = 0.0018$).

6

7 **Correlation between CSF and serum biomarkers with sCD163 (Exp#2)**

8 To better describe the immune profile related to increased sCD163, we investigated any
9 association with sCD163 and other immune molecules in CSF and serum (**Fig.4A-D**). CSF-
10 sCD163 was positively correlated with several biomarkers in CSF, both when examining all
11 PD patients and with early/late separation, even after Bonferroni correction. The strongest
12 significant correlations for CSF-sCD163 observed at all disease stages were those with IL-15
13 ($r = 0.72$) (**Fig.4G**), ICAM-1 ($r = 0.63$), VCAM-1 ($r = 0.61$), and Flt-1 (VEGFR1, $r = 0.51$). Several
14 chemokines were also strongly correlated with CSF-sCD163 in late PD: CXCL10 ($r = 0.52$),
15 CCL4 ($r = 0.51$), and CCL2 ($r = 0.44$) (**Fig.4A-B**).

16 In serum, the sCD163 correlations were weaker and fewer (**Fig.4C-D**): Serum-sCD163 was
17 correlated with CRP ($r = 0.41$), IL-6 ($r = 0.39$), ICAM-1 ($r = 0.34$), and SAA ($r = 0.35$) in all patients,
18 and with TNF- α ($r = 0.55$), IL-12/IL-23p ($r = 0.47$), and VCAM-1 ($r = 0.57$), correlating at late PD.
19 The strong sCD163/IL-15 correlation observed in CSF was absent in serum due to sex
20 discrepancies in CD163 and not in IL-15.

21

22 **Phenotypic related biomarkers (Exp#2)**

23 In CSF, besides sCD163, only IL-15 had a strong negative correlation with MMSE (O+C) and
24 a significant linear regression (**Fig.4E-F,H**) as expected, since sCD163 and IL-15 in CSF were
25 strongly correlated (**Fig.4G**). Interestingly, IL-15 was the only serum biomarker found to
26 negatively correlate and have a significant linear regression with MMSE (O+C) (**Fig.4I**). Other
27 CSF markers also showed a significant negative (but weaker) correlation with cognitive scores
28 MMSE (O+C), although only in late PD: IL-7 ($r = -0.48$), CCL2 ($r = -0.33$), IL-8 ($r = -0.32$), and
29 PIGF ($r = -0.31$) (**Fig.4E-F**). Only serum-VEGF-A showed a significant negative correlation and
30 linear regression with UPDRS III scores (**Fig.4J**). Accordingly, serum-VEGF-A displayed
31 UPDRS III prognostic potential in our mathematical analysis (see below, **Suppl.Fig.5A**). No
32 CSF biomarker correlated with UPDRS III (not shown).

1

2 **Mathematical modeling of sCD163 as phenotypic biomarker in PD (Exp#2)**

3 In order to statistically evaluate the potential of sCD163 and the other assayed markers to
4 predict PD diagnosis (PD vs. HC) and PD phenotypic scores (UPDRS-III, MoCA, MMSE O,
5 and MMSE O+C), we used receiver-operating characteristic (ROC) analysis (area under the
6 curve (AUC) estimates) and linear regression (regression slopes) (**Suppl.Fig.3,5-6**). In CSF:
7 sCD163, VCAM-1, ICAM-1, IL-15, IL-8, SAA, PIGF, and VEGF-C; and in serum: sCD163
8 (female), CRP (female), and VCAM-1 (all) showed statistical power to predict PD (**Fig.4K-L**,
9 **Suppl.Fig3**). Principal component analysis (PCA) of CSF data confirmed sCD163, VCAM-
10 ICAM-1, IL-15, and IL-8 as markers associated with PD diagnosis (**Suppl.Fig4**). In CSF, the
11 best individual markers to predict scores of all three cognitive scales used were sCD163, SAA,
12 and IL-15; while in serum, they were SAA, CRP, and IL-8 (**Suppl.Fig.5-6**).

13 Therefore, our analysis showed the prognostic power of serum- and CSF-sCD163 for PD
14 diagnosis and cognitive scores (in CSF only). However, the specificity and sensitivity of
15 sCD163 were not enough to be used alone. Therefore, we aimed to compute combined
16 biomarker panels to address PD diagnosis and phenotypic scores using three variants of
17 *stepwise forward modeling* with variable probability for biomarkers to enter the model (M), and
18 with sCD163 being forced in M3 (**Suppl.Table6&7**). The best prediction model of serum and
19 CSF biomarker panels were selected and plotted as PD prediction ROC plots (**Fig.4M-N**) or as
20 goodness-of-fit plots for PD phenotypic scores (**Suppl.Fig.7**). M3 including sCD163 together
21 with other independently contributing biomarkers resulted in the best prediction of PD
22 diagnosis, both in serum and CSF (both AUC 0.88). Likewise, M3 including sCD163 (in serum
23 together with IL-15, CRP, CCL2 (MCP-1), PIGF, and IL-7; and in CSF together with p-Tau,
24 IL-7, and IL-8) resulted in the best prediction of MoCA scores with the highest R-square values
25 (serum 0.29, CSF 0.32) (**Suppl.Fig.7B&F**). Therefore, sCD163 in serum and CSF holds
26 promising potential as a significant contributor in a biomarker panel to address PD diagnosis,
27 and cognitive scores, and deserves future investigation.

28

29 **Exploring *in vitro* interaction between CD163 and α -synuclein**

30 Since sCD163 positively correlated with α -syn in CSF, we sought to further investigate any
31 possible relation between them *in vitro*. No signs of direct co-interaction were observed using
32 MST in any condition assayed (**Suppl.Fig.7**). However, incubation of human primary MDMs

1 with increasing concentrations of monomeric and fibrillar α -syn induced macrophage activation
2 and dose-dependent sCD163 shedding (**Fig.5A**), supporting the inflammatory capacity of α -syn
3 and its ability to induce CD163 cleavage, as seen for LPS (positive control).
4 We then evaluated the effect of sCD163 on α -syn uptake using human monocytic THP-1 cells
5 differentiated into macrophages and mouse microglia BV-2 cells to obtain information from
6 the two myeloid cells involved in PD. Cells were incubated with radiolabeled α -syn fibrils alone
7 or with recombinant sCD163 as co- or pre-treatment (30 min) (**Fig.5B**). After 5 min, THP-1
8 cells increased α -syn internalization when co- or pre-treated with sCD163 compared with α -
9 syn alone. In BV-2 cells, the uptake of α -syn increased after 5 and 15 min of pre-treatment with
10 sCD163, while co-incubation increased α -syn uptake only after 45 min (**Fig.5C**). This increased
11 α -syn fibril uptake in THP-1-derived macrophages was specifically associated with full-length
12 sCD163 since LPS removal did not affect uptake, whereas truncation of the sCD163 protein
13 did (**Fig.5D**).

14

15 **DISCUSSION**

16

17 Genetic data suggest that the PD inflammatory component is driven by the myeloid immune
18 compartment, which includes microglia and monocytes/macrophage²⁸. Numerous studies show
19 alterations on immune biomarkers in CSF and serum associated with symptoms in PD
20 patients¹¹. However, these biomarkers are not cell type specific and therefore provide no
21 information on cellular relevance in the disease mechanism. Here, we show that CSF-sCD163,
22 a monocyte/macrophage-specific biomarker¹⁴, increases in late vs. early PD, hence suggesting
23 increasing monocytic activation with disease duration. sCD163 was associated with well-
24 accepted PD biomarkers and inversely correlated with cognitive scores, supporting a role for
25 monocytes in neurodegeneration. Serum-sCD163 was also increased, although only in female
26 patients, suggesting a sex-distinctive monocytic response. This increase in sCD163 levels is
27 indicative of monocytic activation occurring in parallel with variations in cytokines,
28 chemokines, and angiogenic factors. These changes were different in CSF vs. serum, supporting
29 a distinctive immune profile in the brain and periphery. Step-forward regression models and
30 ROC analysis confirmed sCD163 as a predictor of PD and cognitive scores. Additionally,
31 mathematical models confirmed the prognostic potential of sCD163 in combination with other
32 biomarkers in serum and CSF. Interestingly, our *in vitro* studies suggest that α -syn itself can

1 induce macrophage activation and sCD163 shedding, while sCD163 might enhance α -syn
2 uptake by myeloid cells and participate in the clearance of α -syn. In conclusion, our data suggest
3 that sCD163 is a promising biomarker associated with inflammation in PD, thereby supporting
4 a role for α -syn in monocyte activation and sCD163 shedding that could have direct
5 consequences for α -syn processing.

6 Our analysis of the two experiments in the PD cohort showed increased sCD163 in biofluids
7 from PD patients. CD163 is cleaved by ADAM17²², which also cleaves VCAM-1 and ICAM-
8 1^{29, 30}. ADAM17 activity is enhanced by inflammatory signals, such as TLR2/4 activation;
9 therefore, sCD163 levels are related to monocyte activation and associated with severity of
10 diseases with an inflammatory component¹⁴. Indeed, sCD163 is widely used as an inflammatory
11 marker for disease prognosis in multiple disorders including diabetes, asthma, and
12 atherosclerosis³¹. Two diseases genetically related to PD also show increased sCD163: Crohn's
13 syndrome³² and Gaucher disease³³, confirming a shared common myeloid disease mechanism.
14 The inflammatory signals responsible for CD163 shedding in PD are yet unknown, but α -syn
15 may be a contributor since it can activate TLR2/4², which are upregulated in PD patients'
16 monocytes^{4, 34}. Accordingly, we demonstrated sCD163 shedding in human primary MDMs
17 incubated with fibrillar α -syn, confirming the inflammatory ability of α -syn in macrophages³⁵
18 and its relation to the increase of sCD163 in PD.

19 Our data from this cross-section cohort showed increased sCD163 with time from onset,
20 supporting increasing involvement of CD163⁺ monocytes in the different PD stages. Higher
21 CSF-sCD163 levels were not a simple leakage from serum, since the increase was not found in
22 male serum. Furthermore, the estimated amount of sCD163 produced intrathecally was, indeed,
23 elevated in PD. The sCD163 found in CSF can be produced by CD163-expressing meningeal,
24 choroid plexus and perivascular macrophages, as well as by infiltrating macrophages¹⁷⁻¹⁹.
25 CD163 is a myeloid marker whose expression is lost during microglia development and is
26 therefore absent in adult microglia, as recently shown in single-cell RNA studies¹⁵⁻¹⁷. In studies
27 conducted by others and ourselves, an increase in CD163⁺ cells has been observed in brain
28 parenchyma in rodent PD models^{9, 10} and *post mortem* brains of patients with Alzheimer and
29 PD³⁶. Thus, sCD163 could be partially produced by infiltrating CD163⁺
30 monocytes/macrophages and their subsequent local activation. Accordingly, CSF-sCD163 was
31 correlated with CCL2, CCL4, and CXCL10, chemokines involved in monocyte recruitment and
32 previously correlated with PD symptoms³⁷⁻⁴⁰. More importantly, sCD163 was also strongly

1 correlated with regulators of angiogenesis, BBB extravasation, and/or monocyte brain-
2 infiltration or recruitment⁴¹⁻⁴⁵, which have been reported to be increased in PD⁴⁶⁻⁴⁸- namely:
3 ICAM-1, VCAM-1, and VEGF-D in both serum and CSF; and IL-8, IL-15, and PIGF only in
4 CSF.

5 sCD163 is a biomarker widely used to measure an inflammatory component. Accordingly, in
6 PD serum, sCD163 was associated with an increase in the acute phase proteins SAA and CRP,
7 which were previously associated with motor impairment and PD dementia^{37, 49-51}. Moreover,
8 serum-sCD163 also correlated with the pro-inflammatory cytokines TNF- α and IL-6, as well
9 as IL-12/IL-23p40 and IL-15, both elevated in PD serum. IL-12/IL-23p40 is produced by
10 dendritic cells (also CD163⁺) upon TLR activation, whereas IL-15 induces dendritic cell
11 differentiation; thus, both are involved in T cell modulation^{52,53}. IL-12/IL-23p40 was previously
12 found to be increased and important in PD and Crohn's disease^{54, 55}. Taken together, patients'
13 CSF-sCD163 correlated with immune molecules associated with angiogenesis, cell-infiltration,
14 and T cell activation, relating monocyte activation to leucocytes recruitment to sites of
15 inflammation in the brain, whereas serum-sCD163 correlations indicated monocyte activation
16 in relation to pro-inflammatory events. Overall, the immune profile in PD suggested occurrence
17 of an inflammatory events leading towards a permissive environment for recruitment of
18 adaptive and innate immune cells to the brain.

19 Surprisingly, IL-15 was the only biomarker elevated in PD serum and CSF correlating with
20 cognitive scores in both biofluids, thus revealing that IL-15 may be another putative biomarker.
21 However, despite the relevance of IL-15 in BBB permeability, brain immunomodulation, and
22 its connection to mood and memory⁵⁶, our ROC analysis for IL-15's ability to predict PD
23 diagnosis had a lower AUC with higher variation than sCD163. Moreover, in contrast to
24 CD163, IL-15 is produced by a variety of cells including neurons, and is therefore not
25 monocyte-lineage specific like sCD163⁵⁶. Therefore, our data suggest a relevance of IL-15 in
26 PD, but it does not provide information on specific cell types involvement in PD and cognition,
27 and do not reflect the sex difference in the disease, which might be both a disadvantage and a
28 gain.

29 Serum-sCD163 levels were only significantly changed in female PD patients. To our
30 knowledge, only urate has been proposed as a PD biomarker with sex relevance⁵⁷. Sex
31 differences in the immune system are long acknowledged⁵⁸. PD has a sex bias, and immune-
32 related sex differences have been shown in PD⁵⁴. Sex-specific changes in serum-sCD163 could

1 be related to female-male differences in PD incidence⁵⁹ and symptomatic presentation⁶⁰.
2 Accordingly, we previously showed sex-dependent variation in the response of PD blood
3 monocytes *in vitro*³. Therefore, the observed differences could be a result of sex-specific
4 immune divergences with consequences for the risk and presentation of PD.
5 CSF-sCD163 was strongly correlated with the disease biomarkers α -syn, h-Tau, and p-Tau,
6 which have been associated with PD diagnosis, clinical symptoms, and cognition^{61,62}. Our data
7 suggest that in PD, sCD163 increases with α -syn. This correlation could be directly related to
8 the ability of α -syn to induce monocytic activation and sCD163 production, since α -syn has
9 been reported to longitudinally increase with time in PD⁶³. Similarly, h-Tau and p-Tau also
10 increase, probably reflecting progressive neurodegeneration.⁶³ We found that higher sCD163
11 levels were associated with lower cognitive scores, supporting a driving role for monocytes in
12 the cognitive component of PD. This agrees with imaging studies showing that cognitive scores
13 in PD dementia correlated with increased immune activation and reduced cortical glucose
14 metabolism⁶⁴. Furthermore, changes in monocytes seem more relevant in those PD patients
15 with higher risk of developing cognitive problems⁴. Altogether, our data support a relation
16 between monocyte activation and the PD cognitive component.
17 sCD163 function is unclear, but it was shown to potentiate IL-10 expression in allergen-
18 activated PBMCs⁶⁵ and to inhibit T cell activation/proliferation⁶⁶, hence promoting
19 inflammatory resolution. CD163 facilitates hemoglobin-haptoglobin complex⁶⁷ and
20 ADAMTS13⁶⁸ internalization. Our analysis showed no direct binding between CD163 and α -
21 syn, regardless of calcium concentration, suggesting that α -syn is not a direct ligand for CD163
22 (possible co-receptor interactions cannot be excluded). However, our *in vitro* study suggests
23 that α -syn can induce monocyte activation and sCD163 shedding, which in turns increases the
24 capacity of monocytes and microglia to uptake extracellular α -syn. *In vitro*, T cell-internalized
25 sCD163 binds myosin⁶⁹, a molecule involved in phagocytosis⁷⁰. Therefore, sCD163 might
26 induce intracellular pathways that would influence α -syn phagocytosis and thus resolve
27 inflammation. Indeed, sCD163 required time to exert its effect on BV-2 cells, supporting
28 induction of certain intracellular cascades. Otherwise, this delay could be due to species
29 disparities. Further investigation is required to fully understand the sCD163 effect on myeloid
30 response to α -syn during PD.
31

1 The findings of the present study may be somewhat limited by the cross-sectional study design,
2 low numbers of HCs, and potential confounding inflammatory diseases (with anti-inflammatory
3 medication) among study participants. The increase in sCD163 in late PD compared to early
4 PD and HCs, as well as the negative correlation with cognitive scores suggest a relation between
5 sCD163 and PD stages. However, we cannot exclude a possible relation with sCD163 and
6 cognitive decline during ageing in other synucleinopathies and neurodegenerative diseases.
7 Nevertheless, our mathematical modelling proposes a prognostic power for biomarker panels
8 including sCD163 as one of the analytes. However, this has to be examined in a prospective
9 longitudinal study to truly determine the potential of sCD163 as a PD and cognition biomarker.
10 In conclusion, we show a PD-related increase in sCD163 in serum (in females) and CSF,
11 supporting a role for monocytes in the PD immune response. The increase in sCD163 paralleled
12 those of accepted neuronal biomarkers, therefore relating monocytic and neuronal events.
13 Additionally, higher sCD163 levels were associated with lower cognitive scores, indicative of
14 an association between the monocytes' immune response and cognitive decline. The CSF-
15 sCD163 increase was associated with immune biomarkers, suggestive of a permissive BBB and
16 activation of adaptive immune cells. Moreover, our *in vitro* studies suggest that α -syn could
17 activate myeloid cells and induce sCD163 release, which enhances the myeloid cells' capacity
18 to uptake α -syn, indicative of a relevant role for disease progression.

2 **Fig. 1 Identification of sCD163 as a biomarker in PD (Exp#1).**

3 Soluble (s)CD163 levels in CSF **A)** and serum **B)** from healthy controls (HC) or Parkinson's
4 disease (PD) patients at early (<5 years) or late (\geq 5 years since diagnosis) stage. Serum
5 measurements were separated into female (F) and male (M) groups due to a priori identification
6 of sex difference, and include only treated patients. Data are mean \pm SD, and values were log-
7 transformed to achieve normality. CSF-sCD163 for all PD patients correlated with well-
8 characterized neurodegenerative CSF markers: **C)** alpha-synuclein (α -syn), **D)** total Tau (h-
9 Tau), and **E)** phosphorylated Tau (p-Tau); as well as with clinical cognitive scores: **F)** the
10 Montreal Cognitive Assessment (MoCA), **G)** the Mini-Mental State Exam (MMSE) original
11 score (O), or **H)** original plus converted from MoCA (O+C). **I)** CSF α -syn, **K)** p-Tau and serum-
12 sCD163 were correlated and showed a similar trend for CSF levels of **J)** h-Tau. P values for
13 one-way ANOVA with Tukey's multiple comparisons test values, respectively, Spearman two-
14 tail p values (* <0.05, ** <0.01, ***<0.001, ****<0.0001), Spearman r, and best-fit slope with
15 95% confidence intervals are plotted.

16 **Fig. 2 Confirmation of sCD163 as a biomarker in PD (Exp#2)**

17 Soluble (s)CD163 measurements in **A)** CSF and **B)** serum from healthy controls (HC) or
18 Parkinson's disease (PD) patients with early (<5 years) or late (\geq 5 years since diagnosis) status,
19 with serum measurements being separated into female (F) and male (M) groups due to *a priori*
20 identification of sex difference, and include only treated patients. Data are mean \pm SD, and
21 values were log-transformed to achieve normality. CSF-sCD163 for all PD patients correlated
22 with well-characterized neurodegenerative/PD-CSF markers: **C)** alpha-synuclein (α -syn), **D)**
23 total Tau (h-Tau), **E)** phosphorylated Tau (p-Tau), and **F)** Abeta42; as well as with clinical
24 cognitive scores: **G)** the Montreal Cognitive Assessment (MoCA), **H)** the Mini-Mental State
25 Exam (MMSE) original score (O), or **I)** original plus converted from MoCA (O+C). **J)** CSF α -
26 syn, **L)** p-Tau and serum sCD163 were correlated and showed a similar trend for CSF levels of
27 **K)** h-Tau. No correlation was found for serum sCD163 and **M)** Abeta42 in CSF, P values for
28 ordinary or Kruskal-Wallis (non-parametric) one-way ANOVA with Tukey's or Dunn's
29 multiple comparisons test values, respectively, Spearman two-tail p values (* <0.05, ** <0.01,
30 ***<0.001, ****<0.0001), Spearman r, and best-fit slope with 95% confidence intervals are
31 plotted. Further information on cognitive scoring correlations with respect to progression status
32 and covariance can be found in **Suppl. Table 5**.

33

34 **Fig. 3 Screening of other CSF and serum biomarkers (Exp#2)**

35 Sixteen different CSF biomarkers and 27 serum biomarkers from the 40-plex mesoscale assay
36 had values >LLOD (lower limit of detection) and were tested for differences **A-F&L-P)**
37 between healthy controls (HC) and Parkinson's disease (PD) patient groups; or **G-H&R-S)**
38 between PD stages: early (<5 years) and late (\geq 5 years since diagnosis); or **I-K)** concerning
39 treatment (T) status with or without (UT) L-dopa. **I)** MCP-1 (CCL2) and **Q)** IL6 were sex-
40 separated due to a priori identification of sex differences. Twenty-six extra/additional HCs'

1 serum samples from Exp#1 were added for biomarkers unaffected by extra freezing/thaw cycle
2 (**M, O, P, R**). Data are mean \pm SD. P values are shown for unpaired t-test or Mann-Whitney
3 test; for ordinary or (non-parametric) Kruskal-Wallis one-way ANOVA with Tukey's or
4 Dunn's multiple comparisons test values, respectively, as appropriate: * <0.05, ** <0.01,
5 ***<0.001, ****<0.0001. {*} one outlier from early PD was removed based on ROUT Q=
6 0.1%; if including the outlier: p=0.052. Lower and upper limit of quantification (LLOQ and
7 ULOQ). Biomarkers with no differences (or no statistical trend) between groups are shown in
8 **Suppl.Fig 2**.

9
10 **Fig. 4 Correlations of sCD163 with other analytes, biomarker correlations with**
11 **phenotypic scores, and ROC analysis of sCD163 and associated panels for PD diagnosis**
12 **(Exp#2)**

13 **A-B)** CSF- and **C-D)** serum-sCD163 were compared with all 40-plex biomarkers with values
14 above the lower limit of detection (LLOD) measured in CSF (n=16) and serum (n=27),
15 respectively. **A&C)** Spearman correlation p value (the green color shows those with a p value
16 below the Bonferroni-adjusted threshold [p<0.0031 for CSF and p<0.0018 for serum]) and
17 **B&D)** Spearman r values are plotted as heat maps. Correlations are done for all Parkinson's
18 disease (PD) patients or separated as late (\geq 5 years since diagnosis) or early (<5 years since
19 diagnosis) PD status. **E-F)** CSF biomarkers with values above LLOD are correlated with Mini-
20 Mental State Exam (MMSE) (original scores + converted from Montreal Cognitive Assessment
21 (MoCA) (O+C)) and plotted as heat maps for **E)** Spearman p and **F)** r values. Correlations are
22 done for all patients with PD or separated as late (\geq 5 years) or early (<5 years since diagnosis)
23 PD status. **C)** CSF IL-15 had the strongest correlation with MMSE O+C; plotted with the
24 Spearman p and r [95% confidence interval (CI)] and the equation for the linear regression with
25 a slope significantly different from 0. **D)** IL-15 was the only biomarker in serum with a
26 significant correlation and linear regression with MMSE O+C. **E)** IL-15 in CSF had a strong
27 correlation and linear regression with CSF-sCD163. **F)** Serum VEGF-A was the only biomarker
28 with a significant correlation and linear regression with the Unified Parkinson's Disease Rating
29 Scale three (UPDRS III) score. Spearman two-tail p values (* <0.05, ** <0.01, ***<0.001,
30 ****<0.0001). **K-N)** ROC curves for prediction of PD related to sCD163: **K)** CSF-sCD163
31 alone, **L)** serum-sCD163 alone when separated by sex, **M)** CSF M3 biomarker panel including
32 sCD163, h-Tau, Abeta42, SAA, and VEGF-A x10, **N)** serum M3 biomarker panel including
33 sCD163, VEGF-D/100, VCAM-1/10,000, Flt1/100, IL-15, IL-10, and MIP1 β /100. Area under
34 the ROC curve (AUC), confidence interval (CI). ROC curves for other biomarkers with p <
35 0.05 are shown in **Suppl.Fig.3**.

36
37
38 **Fig. 5 sCD163 increases α -syn uptake in myeloid cell lines; and α -syn induces sCD163**
39 **shedding in primary MDMs**

40 The interaction between α -syn and sCD163 was studied *in vitro* **A)** sCD163 shedding in primary
41 human monocyte-derived macrophages from four human donors after stimulation with LPS
42 (positive control) or dose-dependent stimulation (0.1 μ M, 1 μ M, or 5 μ M) with monomeric
43 (MONO) or pre-formed fibrils (PFF) α -syn for 1, 6, or 24 hours, respectively. **B)** Experimental
44 design used in **C)**: BV-2 and differentiated THP-1 cells were incubated at three different
45 conditions: **1.** With iodine-radiolabeled α -syn (125 I α -syn) PFF (control); **2.** Co-incubated with
46 125 I α -syn and sCD163 (5 μ g/mL); and **3.** Pre-treated with sCD163 (5 μ g/mL) 30 min prior 125 I

1 α -syn addition. Cells were incubated at 37°C (5, 15, and 45 min) after α -syn addition and
2 collected for evaluation of α -syn internalization. Radioactive counts per minute (CPM) on
3 differentiated THP-1 and BV-2 cells were normalized to α -syn average counts (treatment 1)
4 and shown as % of control internalization/binding. Endotoxin levels in recombinant sCD163
5 were measured and corresponded to 0.030EU/mL (according to concentration used). **D**) The
6 sCD163-mediated uptake of MONO and PFF α -syn by THP-1 cells was evaluated after 5 min
7 of incubation of full-length (domain 1-9) “LPS-free” sCD163 (LPS-removal treatment on the
8 sCD163 protein sample resulting in 0.00017EU/mL endotoxin, according to concentration
9 used) or a truncated version (domain 1-5) of sCD163, where LPS was also removed. Statistics:
10 **A**) Paired t test; **A-D**) two-way ANOVA followed by post-hoc Tukey’s multiple comparison
11 test when appropriate. P values are given in intervals according to the number of symbols, e.g.
12 * <0.05 , ** <0.01 , *** <0.001 , **** <0.0001 . Symbol explanation: **A**) § different from 5 μ M in
13 PFF; † different from all other in the same group; €PFF different from MONO in the same
14 dose; ¤ different from 0 μ M in PFF. **A-D**) * different from control (**A**) UT or **C-D**) α -syn alone)
15 at the same time point. **C**) \$ different from all other treatments at the same time-point; #
16 different from adjacent time point in the same treatment; [##] co-treatment different from 5
17 min. Data are shown as mean \pm SEM. Illustration was made using Biorender.
