18 **Abstract**

19 The world searching for hope has already experienced a huge loss of lives due to COVID-19
20 caused by SARS-CoV-2 started in Wuhan, China. There are speculations that climatic
21 conditions can slowdown the transmission of COVID-19. Findings from the early outbreak
22 indicated the possible association of air temperature and relative humidity in COVID-19
23 occurrence in China. Current study focused on whether climatic conditions (temperature and
24 relative humidity) are having any influence in the occurrence of COVID-19 when the
25 outbreak has been classified as pandemic. To determine the effect of daily average
26 temperature and average relative humidity on log-transformed total daily cases of COVID-19,
27 polynomial regression as a quadratic term and linear regression were done. Linear regression
28 analysis was also carried out to explore the same effect on selected countries. Present study
29 observed no correlation between the climatic conditions (the daily average temperature and
30 relative humidity) and the number of cases of COVID-19. Similar result was found in relation
31 between daily average temperature and average number of cases per day in country-wise
32 analysis. However, about 93.5% cases of COVID-19 occurred between 1⁰C to 16⁰C and the
33 average number of cases per day was lower in high temperature country than low temperature
34 country with exceptions. The minimum effect of summer temperature may not be effective to
35 control the pandemic rather need to apply the control measures of COVID-19.

36 **Keywords:** COVID-19; temperature; relative humidity; contact; transmission

37

38 **1. Introduction**

39 COVID-19 caused by SARS-CoV-2 is an enveloped, positive sense single stranded
40 RNA virus of the family *Coronaviridae*, a major pathogen of respiratory illness (Pal et al.,
41 2020). Since the outbreak of COVID-19 in Wuhan, China on the late December, 2019 (Lu et
42 al., 2020), it has rapidly spread throughout China and all over the world (Gorbalenya, 2020;
43 Arab-Mazar et al., 2020; Chen et al., 2020; Huang et al., 2020; Wang et al., 2020a; Holshue
44 et al., 2020; Wang et al., 2020b). The major contributing factor for this new epidemic was the
45 importation of COVID-19 cases from epidemic countries. So far, more than 200 countries
46 and territories have been affected with 1,395,136 confirmed cases and 81,580 deaths,
47 together with cessation of normal social operations and massive economic loss (WHO,
48 2020a). Earlier, WHO, observing the current situation across the world, declared COVID-19
49 as “a pandemic” (WHO, 2020b).

50 The experience of SARS and MERS outbreak differs with COVID-19 in
51 extensiveness of spread, and death rate but finds similarity in sign-symptoms and
52 transmission pattern (Wang et al., 2020c). Seasonality of respiratory viral disease is an old
53 theme that recognized winter as an important factor of influenza like diseases transmission
54 (Sobsey and Meschke, 2003; Wolkoff, 2018). The transmission of virus is under the influence
55 of climate conditions e.g., temperature and relative humidity (Hemmes, et al., 1960, Dalziel,
56 et al. 2018). Several studies found droplet, aerosol, and direct and indirect contact can act as
57 the major factors in the transmission of SARS like viruses (Peng et al., 2020; Rodríguez-
58 Morales et al., 2020; To et al., 2020). Survivability of SARS virus in environment and
59 surfaces is associated with temperature and relative humidity (Chan et al., 2011). High
60 temperature reduces aerosol but cannot inhibit contact transmission immediately (Lowen et
61 al., 2008). SARS-CoV-1 and SARS-CoV-2 are able to survive in air and surface for sizable
62 time periods, thus enabling the virus more capable to affect human (VanDoremalen et al.,
63 2020). Survival of SARS-CoV-2 in air and surfaces associated with climate with is still
64 unclear.

65 Although some studies found relationships of climatic conditions with the occurrence
66 of COVID-19 cases (Wang et al., 2020d, Wang et al., 2020e, Zhu and Xie, 2020), they had
67 limited option to include high temperature country as the outbreak was mainly circulating in
68 temperate zone during the early stage of outbreak. Therefore, this study aimed to understand
69 the possible role of temperature and relative humidity in the occurrence of COVID-19 in 57
70 countries from tropical and temperate zone.

71 **2. Materials and methods**

72 **2.1. Data**

73 Countries having at least 500 cumulative cases by March 28, 2020 were selected
74 for study. Once a country reported at least 10 cases on particular day was considered for data
75 recording for that day. Date wise metrological parameter, like temperature and relative
76 humidity were obtained from 57 countries to find out a possible link between COVID-19
77 cases and metrological data. The highest and the lowest temperature were recorded and the
78 average of these two data was considered as the daily temperature. The daily relative

79 humidity was recorded as AM (Before mid-day) and PM (After mid-day). The average was
80 considered as the daily relative humidity.

81 **2.2. Source of Data**

82 We extracted information from national and international reports of the outbreak and
83 metrological data from relevant websites. The daily case reports were documented from
84 “WHO”, “Worldometer”, and “Kaiser Family Foundation” websites (WHO, 2020c;
85 Worldometer, 2020; KFF, 2020). The daily temperature and relative humidity data were
86 recorded from “The Weather Channel”, “Timeanddate” and “Accuweather” websites (The
87 Weather Channel, 2020; Timeanddate, 2020, Accuweather 2020). All the data taken for this
88 study were from January 9, 2020 to March 25, 2020.

89 **2.3. Statistical Analysis**

90 Natural Log-transformation was performed on total number of daily COVID-19
91 confirmed cases of 57 countries. Polynomial regression as a quadratic term was done to find
92 out the relationship between daily average temperature and log transformed daily cases of
93 COVID-19 as we observed a non-linear relationship during initial data exploration (Bradley
94 and Srivastava, 1979). However, the linear regression was used to find out the effect of daily
95 average relative humidity on COVID-19 cases (Matthews, 2014). For a certain country, the
96 natural log of the average number of cases per day was used, and the linear regression was
97 done to find out the effect of temperature and relative humidity on the occurrence of COVID-
98 19 cases.

99 **3. Results**

100 The data on average temperature, average relative humidity, and log transformed
101 confirmed cases per day of COVID-19 in 57 countries are listed in Supplementary Table.
102 Here, we included 444,405 cases from 57 countries (January 9, 2020 to March 25, 2020). The
103 daily average lowest and highest temperature was respectively -5°C in Finland and 29.9°C in
104 Thailand. Percent relative humidity varied from 30 in Saudi Arabia to 78.8 in Indonesia. Data
105 suggest relative humidity was fluctuating with large deviation in every country. Except China
106 (January, February, March), Italy (February, March), Iran (February, March), South Korea
107 (February, March), France (February, March) and Japan (February, March) all other countries
108 had COVID-19 cases in March. In China, the early outbreak was in January when average
109 cases per day were lower than in February and March. Similarly, Italy, Iran, South Korea,
110 France and Japan had lower average cases per day in February compared to March. Among
111 the countries, Italy had the lowest and highest average cases per day respectively in February
112 (average monthly temperature 7.5°C) and March (average monthly temperature 9.4°C).

113 In polynomial regression as a quadratic term, no correlation ($R^2 = 0.031$) between the
114 daily average temperature and the number of cases of COVID-19 was found. The analysis
115 showed that $\lg N$ of cases increased as the average temperature rose and started to decline
116 moderately when temperature reached the peak (Fig. 1). The analysis showed that 98.8%
117 proportionate cases occurred between -0.5°C to 30°C and, more restrictively, 93.5% cases
118 occurred between 1°C to 16°C (Fig. 1). The average relative humidity was also not correlated

119 ($R^2 = 0.0272$) with the occurrence of COVID-19 in linear regression (Fig. 2). However, most
120 of the low temperature countries had relatively higher average number of cases per day than
121 high temperature countries (Fig. 3). There were also exceptions. For country-wise analysis,
122 average monthly observations were used for each country. In linear regression country-wise
123 analysis revealed no correlation ($R^2 = 0.0602$) between temperature and occurrence of
124 COVID-19 cases per day (Fig. 3).

125 **4. Discussion**

126 This is the first study that consider the pandemic situation (57 countries including
127 high and low temperature countries) to draw conclusions on possible association of
128 temperature and relative humidity with COVID-19 cases. Therefore, the findings of this study
129 demand importance. No correlation between the daily average temperature and the
130 occurrence of cases of COVID-19 was observed. Earlier studies found correlation between
131 temperature and the occurrence of COVID-19 (Wang et al., 2020d, Wang et al., 2020e, Zhu
132 et al 2020). Wang et al., (2020d) showed that most COVID-19 cases in China occurred
133 between 0°C to 10°C . Another study analyzed data (January 20, to February 4, 2020) of
134 COVID-19 cases and revealed that the majority of cases occurred with temperature around
135 10°C (Wang et al., 2020e). But all these studies obtained data from the early stage of the
136 outbreak, at best till February when most of the affected countries were in winter. In our
137 study, temperature varied from -24°C to 30.5°C in 57 countries. The huge variation of
138 temperature in analysis found no correlation with COVID-19 cases. We found 93.5%
139 COVID-19 cases were between 1°C to 16°C as most of cases were from China, Italy, USA,
140 Iran, Germany, France and Spain where the duration of outbreak is prolong (Supplementary
141 Table).

142 In country-wise analysis, no correlation was observed between average daily
143 temperature and average per day cases of COVID-19. However, in general, countries having
144 high temperature experienced relatively lower occurrence of COVID-19 (Fig. 3) with
145 exceptions. This is may be due to high temperature countries are at early stage of outbreak.
146 With the progress of outbreak the number of cases may increase exponentially if proper
147 control measures are not taken. The transmission was exponential in some developed low-
148 temperature countries like USA, Italy, Spain, Germany, and France where large scale
149 community transmission was reported (WHO, 2020a). On the other hand, similar countries
150 like South Korea, Japan took steps during early stage of the outbreak being quite successful
151 in limiting virus transmission (Financial Times, 2020). The average daily temperature in
152 Hong Kong (21.7°C) and Brazil (23.1°C) was quite similar, but Brazil had relatively higher
153 number of daily average cases (Supplementary Table). These findings suggest all countries
154 for applying proper control measures. However, these exceptions can be interpreted taking
155 into consideration that virus transmission in an outbreak largely depends on the interventions
156 taken by each particular government. In addition, duration of outbreak, population density,
157 other metrological variables, level of awareness in people, and medical facilities are not same
158 for all countries. Among so many factors, transmission of COVID-19 virus from
159 asymptomatic is carrier very important. A study has been carried out on the passengers of
160 Diamond Princess cruise ship, where 50.47% COVID-19 patients were asymptomatic carrier

161 (Mizumoto et al., 2020).Additional study is required to consider many more variables. A
162 variable relative humidity was considered in our study. Though Wang et al., (2020d) found a
163 correlation between relative humidity and the occurrence of COVID-19 cases, we could not
164 confirm this association.A recent study in China Jakarta, Indonesiaalso showed no effect of
165 relative humidity on COVID-19 occurrence (Tosepu et al., 2020). This observed variation in
166 results may be due to a variation in the investigated time periods and data size in the different
167 studies.In addition we observed inconsistent relative humidity in most of the countries in our
168 study.

169 The stability SARS virus was studied in laboratory, at 22-25°C SARS-CoV is stable
170 up to five days on plastic surface while rapidly losing activity at 38°C or more (Chan et al.,
171 2011). SARS-CoV-2 survive in air (3 hours), on plastic and stainless steel surfaces (up to 72
172 hours) thus contact transmission is facilitated (Van Doremalen et al., 2020), but
173 investigations of this type associated temperature and humidity are scarce for SARS-CoV-2.
174 Preliminary evidences indicate that high temperature affect virus transmissibility through
175 droplet and aerosol (Lowen et al., 2008), but contact transmission cannot be ignored (Van
176 Doremalen et al, 2020). Therefore, “high temperature” itself is not enough to combat the
177 pandemic. The primary epicenter in Wuhan, Chinaalready has proved that the virus is
178 controllable in a low-temperature region (WHO, 2020d). We suggest that all countries should
179 follow control measures similar to those adopted in China, taking into account that
180 temperature increments will not be enough.

181 **5. Conclusions**

182 To the best of our knowledge, this is the first study describing temperature and relative
183 humidity has no major effect to describe on the current COVID-19 pandemic. More studies
184 needed to which variables are contributing most. Current study suggests all countries not to
185 depend on summer rather to implement possible all control measures of COVID-19.
