24 ABSTRACT

25 Background

Despite high coverage and successes in malaria control strategies, some areas of Tanzania have indicated stagnantion or revesal of malaria burden. In malaria research, most studies are designed to assess drivers of malaria transmission focusing only on one dimension, single location while very few studies assess multiple components and their interactions at once. This article describes the protocol used to assess intrinsic and extrinsic drivers of persistent malaria transmission (hotsposts) in four regions from northwestern (Geita and Kigoma) and southern (Ruvuma and Mtwara) Tanzania.

33 Methods

This cross-sectional study was conducted between July and November 2017 in eight districts 34 (two from each region). Based on the health facilities records, two villages were selected 35 from each district. The study assessed five components individually and their linkages: 36 37 socio-economic and malaria risk factors, parasitological, entomological, socioanthropological and health system factors. Households (HHs) and household members were 38 39 enumerated, socio-economic status and risk factors associated with malaria transmission were assessed. A total of 120 HHs were sampled from each village where malaria testing 40 using rapid test and microscopy were done and blood spots on filter papers for genetic 41 42 studies were collected. Heads of HHs were interviewed to capture information on 43 knowledge, attitude, practice and beliefs towards malaria and its control. Assessment of adult mosquitoes in 25 HHs in each village and complimented with assessment of immature 44 45 mosquitoes through larvae was conducted. The performance of the health system was

assessed with respect to Information on availability, accessibility, affordability and quality of
malaria prevention and case management services were collected from these health
facilities.

49 Discussion

The proposed analysis plan and results from this study are expected to determine factors potentially responsible for persistence of malaria (hotspots) in the study areas. Rather than the traditional methodology of focusing on one metric, the approach proposed here triangulates observations from all five components, highlighting understanding of potential drivers while studying their complex interactions and map spatial heterogeneity. This study will provide an important framework and data which will guide future studies and malaria surveillance in Tanzania and other malaria endemic countries.

57 Key words: malaria, malaria hotspots, malaria surveillance, Tanzania

59 BACKGROUND

Recent reports have shown a dramatic decline in malaria around the world and across sub-60 61 Saharan Africa (SSA)(1). However, the 2015-2016 Tanzania demographic and health survey and malaria indicator survey (TDHS-MIS) showed re-emergence of malaria with an increase 62 from its 2012 prevelence (among children 6-59 months old) of 9.8%(2) to 14.8%(3). This highly 63 heterogenous disease continues to place a heavy burden in most parts of mainland 64 65 Tanzania, including the southern and north western regions with prevalence rates in some 66 regions exceeding 50% and high mortality rates in young children(3,4). Although the results from the different national surveys have demonstrated an upward trend in intervention 67 coverage, particularly long-lasting insecticidal nets (LLINs) (>80%) and a substantial increase 68 69 in use rate (66%), this is not reflected in the trends of disease burden in some parts(3). It is evident that the current interventions pioneered by the Tanzanian national malaria control 70 71 programme (NMCP) might be insufficient in some areas and less likely to lead to the 72 elimination target of malaria in these poverty stricken areas. In the fight against malaria and in order to reduce the disease burden, there might be a need for i) complimentary 73 strategies; and ii) strategic and innovative deployment of available tools, in order to reach 74 75 the national and international malaria control/elimination goals.

76

Recent successes in malaria control efforts relying on insecticide-based vector control
interventions such as LLINs (5–11) and indoor residual spraying (IRS) (12–15), are threatened
by rapid expansion of insecticide resistance in vector population. This has affected many
countries in Africa, and is mounting pressure on the advancing global malaria elimination

efforts(16-20). To make the long term goal of malaria elimination in Africa a reality, it is 81 82 important that the effectiveness of existing control interventions is maintained and supplemented with additional proven strategies for vector control, case management and 83 behavioural change. Larval control and house improvement could be important 84 interventions in both urban and rural settings, particularly in areas where majority of the 85 population are at risk(21-25). In addition, improved longitudinal quality assured 86 87 disease/vector surveillance systems, such as the community-based trapping system have become increasingly necessary for identifying and mapping the densities of sparse residual 88 vector populations and for monitoring and evaluating the impact of interventions upon 89 them (26–31). 90

91

92 The intensity of malaria transmission and the disease burden are influenced by a complex array of environmental, ecological, socio-demographic and climate factors and this complex 93 interplay of biotic and abiotic factors should be taken into account in an attempt to assess 94 the impact of the recent malaria interventions. Traditional approaches, assessment of 95 factors related to transmission and burden is usually designed focusing on few components 96 without considering the interlinks and interactions, which play between such attributes. This 97 is mainly due to financial or logistic constraints, but also partly to ignoring or failure to fully 98 consider the importance of the existing interlinks among different factors responsible for 99 and maintenance of malaria transmission. Congruent temporal and spatial data over long 100 periods are critical for determining key factors affecting malaria transmission at micro and 101 macro-geographical levels, but such long-term data is commonly lacking. This results into 102

103 limited evidence with high level of uncertainty which sometimes fail to provide an accurate 104 measure of the magnitude of the disease risk and guidance on stratification of disease 105 burden which is a prerequisite in setting up control strategies with most impact.

106

Previous surveys have shown variation in malaria prevalence in areas with small proximities 107 and factors related to such patterns are not clearly known(3,32,33). In the absence of 108 109 longitudinal data, stratification of malaria transmission can alternatively be attained through 110 macro and micro-mapping of malaria transmission and disease burden, and documenting key factors responsible for heterogeneity of malaria. That need to cover important aspects 111 112 including community-based indicators, profile of the disease epidemiology, coverage and utilization of interventions, vector biology and behaviours, and performance and readiness 113 114 of the exisiting health system in disease management.

115

This article describes the protocol used to determine the intrinsic and extrinsic drivers of 116 persistent malaria burden in selected areas of Tanzania mainland. It aimed at providing data 117 on different factors which could be potentially driving the current pattern of malaria 118 transmission and are possibly associated with persistent and/or reduced malaria burden and 119 the heterogeneity currently observed in Tanzania. The findings will be used to support 120 NMCP and its stakeholders in the stratification of malaria burden and developing targeted 121 122 control interventions required to push malaria further down to reach elimination target by 2030. The data will also support future studies/surveillance of persistent malaria burden in 123 different parts of Tanzania. 124

125

126 Study objectives

The main objective of this assessment was to determine the intrinsic and extrinsic drivers of 127 128 persistent malaria burden in selected parts of Tanzania. Specifically, focusing on testing existence of micro scale spatial variations of parasite prevalence, the distribution, type and 129 abundance of malaria vectors. Addition to that, the study assessed socio-economic, 130 131 anthropological and health system factors associated with persistence of malaria in regions which had high level of interventions in the past decade. Interlinks between the five 132 components will be studied to understand their interactions and draw conclusions which 133 have to be taken into account when assessing these relationships. 134

135

136 Methods

137 Study Sites

This study covered eight districts from four regions; Geita, Kigoma, Mtwara and Ruvuma regions (Figure 1), with persistently high malaria transmission as shown by different surveys conducted in Tanzania between 2011 and 2017. Such surveys include the Tanzania HIV and Malaria indicator survey (THMIS 2011-12) (32), Tanzania demographic and health survey – Malaria Indicator survey (TDHS-MIS 2015-2016) (34) and the 2015/2016 school malaria prevalence surveys (SMPS) (35) (Figures 2 and 3).

144

145 Based on the 2011-12 THMIS, the highest malaria prevalence (by malaria Rapid Diagnostic 146 Test(mRDT)) was observed in the Southern (20.6%), Western (16.7%) and Lake (14.8%)

147 zones(2). A similar pattern was observed 3 years later during the 2015-16 TDHS-MIS which 148 showed that the highest prevalence was within the same zones; Western (27.7%), Lake 149 (23.5%) and Southern (18.8%)(3). Regions with high (>10%) prevalence during the 2011-12 150 survey included (in descending order); Geita (31.8%), Lindi (26.3%), Kigoma (26.0%), Mara (25.4%), Mwanza (18.6%), Mtwara (17.4%), Morogoro (13.0%) and Ruvuma (12.0%)(2). The 151 same set of regions presented high prevalence in 2015-16 in additional to Kagera, Pwani, 152 153 Tabora, Shinyanga, Mwanza, Katavi and Simiyu(3). The results of SMPS brought a similar set 154 of zones and regions affected mostly with malaria. Regions with the highest prevalence 155 included Geita (53.7%), Pwani (48.4%), Mwanza (40.0%), Katavi (39.9%), Mara (36.4%), Mtwara (36.2%), Shinyanga (35.1%), Kagera (31.1%), Simiyu (31.0%), Lindi (30.3%), Kigoma (30.3%), 156 Tabora (30.0%) and Ruvuma (22.6%)(35). The findings of these surveys indicated that some 157 158 regions consistently maintained high malaria transmission in the past 5 years, including Geita 159 (Lake zone), Ruvuma and Mtwara (Southern zone) and Kigoma (Western zone) (Figure 1).

160

Thus, four regions were selected for the study and two districts with high and low malaria 161 162 prevalence based on the SMPS of 2015/2016 were selected from each region (Figure 1); Buhigwe and Uvinza (Kigoma), Mtwara DC and Nanyumbu (Mtwara), Nyasa and Tunduru 163 (Ruvuma) and Nyang'hwale and Chato (Geita). Districts in Geita region were chosen with an 164 added criterion of taking part in IRS programme which was done shortly before this study. 165 Two villages with high malaria burden, based on the number of cases reported by health 166 facilities in 2016, were selected from each district, making 16 villages. Health facilities serving 167 the respective villages were also visited for the health system survey. 168

169

170 Study design

171 This was a cross-sectional survey which evaluated entomological, parasitological, health

- 172 systems, socio-economic and socio-anthropological components (Figure 4).
- 173

174 Plannning and organization of the study teams

175 Training of the teams on the study protocol and the tools was done before initiation of the 176 study; and was done separately according to the component to be implemented. Dry runs were conducted in Magoda village in Muheza district, Tanga region. Community members of 177 Magoda village have experience of taking part in different surveys of malaria transmission 178 for the past three decades (37). The demographic and socio-economic (census) team 179 180 conducted first the dry run, other teams conducted the dry runs one week later using the 181 data generated by the census team. The exercise was followed-up by a post-test assessment to sort out any issues encountered during the dry runs before data collection was launched. 182 The main study was conducted between July and November 2017 following a similar order. 183 In each village, the teams conducted the survey in 3 to 4 days and the entire survey took 184 about 65 days. 185

186

187 Sample size, sampling procedures, and collection of data and samples

188 To create a sampling frame, a demographic census was undertaken and all households (HHs)
189 from the selected villages were enumerated, and each member of the HH was given a

- unique identification number. Systematic sampling was used to identify HHs to be includedin other components of the study as described below.
- 192

193 **Demographic and socio-economic survey**

A demographic census was undertaken in the selected villages whereby all HHs (between 194 200 to 700HHs per village) were enumerated and assessed for socio-economic status (SES) 195 196 and risk factors associated with malaria transmission. Demographic data including name, sex, date of birth, education status and occupation were collected for all members residing 197 in each HH. Malaria risk mapping was undertaken, and it included collection of data on the 198 housing quality based on construction materials, presence of eaves and open windows, 199 location of the HH in the village and environmental features associated with malaria 200 201 transmission (e.g. mosquito breeding sites). Furthermore, information on malaria 202 prevention strategies [e.g. screened windows, availability and use of bed nets (ITNs and LLINs), IRS and intermittent presumptive treatment in pregnancy using SP (IPTp-SP)] were 203 collected. The SES of each HH was also assessed and it focused on ownership of assets such 204 as livestock, farming land, electronic equipment (e.g. mobile phones, radio, television), 205 206 means of transport (e.g. bicycle, motorcycle), source of energy for cooking and lighting, source of drinking water and type of latrines. 207

208

209 Parasitological survey

A total of 120 HHs from each village were sampled from the census list and all members from
the selected HHs were enrolled in the parasitological survey that was conducted at a central

212 point. A comprehensive parasitological assessment was conducted to obtain baseline data 213 on malaria transmission intensity in the study population. A parasitological questionnaire 214 was used to collect information on demographics, malaria prevention, clinical and treatment 215 history. Additionally, vital signs and anthropometrics measures were taken, splenomegaly was evaluated for children up to 12-years. Blood samples were collected by finger prick, thin 216 217 and thick smears were prepared, malaria rapid test (mRDT) (Carestart[™] Somerset, NJ USA) 218 was done for detection of malaria parasites and haemoglobin levels were evaluated using HaemoCue® machines. Dried blood spots (DBS) on filter papers were collected for further 219 220 parasites and host genetic factors analysis of malaria that might affect susceptibility/resistance to malaria parasite infection and clinical disease. Participants with 221 mRDT positive results were treated according to the National malaria treatment 222 223 guidelines(38) and participants thought to need further investigation and management were referred to the nearest health facility. 224

225

226 Socio-anthropological survey

A structured questionnaire was used to collect quantitative data while qualitative data was collected through focus group discussions (FGDs) and in-depth interviews (IDIs) using interview topic guides. Heads of the HHs which were involved in the parasitological survey were interviewed to capture information on knowledge, attitude, practices and beliefs (KAP&B) towards malaria and its control. Specifically, respondents provided information on key issues such as malaria transmission, signs, symptoms and treatment; malaria prevention (e.g. use of bed-nets and chemoprevention such as IPTp) and health seeking behaviour. For

234 the qualitative study, two FGDs were conducted in each village, whereby each FGD included 235 8-12 individuals aged >18 years (male and female participants separately). The information collected during FGDs included; knowledge on malaria (its transmission, signs, symptoms 236 237 and treatment), community's practices and attitudes on malaria prevention, e.g. use of bednets, use of antimalarial drugs and health seeking behaviour. Participants of the FGDs were 238 239 randomly selected from HHs which were not involved in the parasitological survey and 240 KAP&B interviews. Indepth interviews were also undertaken with at least two officials involved in malaria control at the district level, including the district medical officer and/or 241 242 district-malaria coordinators/focal persons. Repondents provided information on availability, accessibility and utilization of malaria prevention, treatment and control 243 services in their areas. 244

245

246 Entomological survey

247 A sub-sample of 25 HHs were selected randomly (from the census list) in each of the study villages for entomological assessments. The selected HHs had open eves, were close to the 248 249 breeding sites and with medium size windows and/or with no mosquito netting material. 250 Among the 25 HHs; 20, 10 and 5 HHs were randomly selected for collection of indoor host 251 seeking malaria vectors using the Centres for Disease Control (CDC) light traps (John W Hock 252 Co, Gainesville, FL, USA), indoor resting malaria vectors using pyrethrum spray catch and 253 outdoor biting malaria vectors using tent traps, respectively. Assessment of immature 254 mosquitoes was also done through larvae search. Details of each collection method used are provided below: 255

Light Trapping: After obtaining a written informed consent from the home owner, a CDC light trap was installed at the foot of a sleeping place occupied by a family member sleeping under an insecticide-treated bed-net as described previously (39). In brief, trapping was done in 20 HHs from each village for three consecutive nights and the traps were set between 18.00 and 19.00 hours, and retrieved the following morning between 06:00 and 07:00 hours.

Pyrethrum Spray Catches: Spray catch collection was done for one day in 10 HHs from each study village. The HHs used here were a sub-sample of the same HHs used for CDC light trapping. Mosquitoes were collected by spraying a non-residual crude pyrethrum solution premixed with kerosene at the concentration of 0.5%. Food and small items were removed from the houses and white cotton sheets were spread to cover the floor and large furniture. Ten to fifteen minutes after spraying, researchers collected knocked down mosquitoes and preserved them in petri-dishes for later identification and score of their physiological status.

Furvela Tent Trapping: These were used for three nights consecutively in 5 HHs from each village. Furvela tent traps consisted of a tent and a CDC light trap with the light bulb removed. A volunteer slept in the tent with a small opening in the tent door to allow host odours to escape and attract mosquitoes as previously described (40). The traps were set each night between 18:00 and 19:00 hours and retrieved the following morning between 06:00 and 07:00 hours.

Larval Surveillance: Mosquito larval breeding habitats were mapped using global positioning
system (GPS) in Open data kit (ODK) (GPS; Trimble Geoexplorer II, USA) while Larvae search
was conducted using the World Health Organization (WHO) 350 ml standard mosquito

dipper. Depending on the size of the aquatic habitat, five to twenty dips were taken from each larval habitat after physically inspecting the habitat for the presence or absence of mosquito larvae. Five dips were taken in small larval habitats of $\leq 1 \text{ m}^2$, 10 dips for mediumsized habitats (2–15 m²) and 20 dips for relatively large habitats (> 15 m²). The immature mosquitoes were classified into three categories as; early instars (first and second stage larvae), late instars (third and fourth stage larvae) and pupae, after which they were sorted by genus, counted and recorded.

Mosquito identification: Mosquitoes collected were transported to the field laboratory 285 which was set up in each village (within a school or village administration office) and 286 identified to species using morphological criteria (41). Malaria vectors were further classified 287 according to their abdominal status as unfed, blood-fed, semi-gravid or gravid. Female 288 289 mosquitoes (Anopheles gambiae complex and An. funestus group) were stored in individual Eppendorf tubes containing silica gel desiccant for sibling species identification, detection of 290 sporozoite and molecular markers of insecticide resistance. All non-malaria mosquitoes were 291 identified, counted and discarded. 292

293

294 Health system survey

The health system (HS) assessment survey targeted all health facilities serving the study villages including Accredited Drug Dispensing Outlets (ADDO), dispensaries, health centres and district hospitals where village members were getting initial consultations and/or refferal services. The facilities include those located within the study villages or nearby. The assessment was based on the WHO recommended guidelines on service provision

300 assessment for malaria (SPAM)(42) which collects information on availability, accessibility, 301 affordability and quality of malaria prevention and case management services. Data collection tools, adopted from the WHO guidelines, were used for this assessment. These 302 included, Health facility Profile, Consistency check, Antenatal clinic (ANC), Out-patient 303 department (OPD), Inpatient department (IPD), Laboratory and Pharmacy questionnaires. 304 Data were collected from the facilities through observations and documentary review, 305 306 health workers interview and exit interviews with clients. A critical assessment of different units/sections and departments at the health facilities (including outpatient and inpatient 307 departments, laboratory and reproductive child health – RCH units) and within ADDOs was 308 done. Health workers interviewed included the facility in-charges and heads of units while 309 exit interviews were held with patients'/care-givers who were attended at the mentioned 310 311 units on the day of the visit (interviewees were selected based on history of fever or diagnosis of malaria). In summary, observations were done for 12 patients attended at each 312 facility including; 5 malaria patients from outpatient department, 5 from RCH and 2 patients 313 who received artesunate injection for treatment of severe/complicated malaria. 314

315 Laboratory Analyses

316 **Detection of malaria parasites by microscopy and Polymerase chain reaction (PCR)**

Blood smears and DBS sample were sent to laboratory in Tanga for further analysis. The blood slides were dried at room temperature, thin film fixed with 99% Methanol and the smears were stained with 5% Giemsa solution for 45 minutes the following day while in the field. Stained blood slides were then packed and shipped to the laboratory in Tanga where the smears were examined under high power objective (oil immersion objective) for

identification and quantification of malaria parasites. Asexual and sexual parasites were counted against 200 and 500 white blood cells (WBCs), respectively. Parasite density was obtained by multiplying the counts by 40 or 16 for asexual and sexual parasites, respectively; assuming each micro litre of blood contained 8000 WBCs(43). A smear was declared negative after examining 200 high power fields.

DNA was extracted from all microscopy positive DBS samples using QIAamp DNA Mini Kits (QIAGEN, Valencia, CA, USA) as described by the manufacturer, and stored at -20°C before analysis. Other samples will be extracted later using the same methods and the photoinduced electron transfer PCR (PET-PCR) assay will be used to detect the presence of submicroscopic infections. The assay relies on self-quenching primers for the detection of *Plasmodium spp* using *Plasmodium* genus and species specific primers as previously described (44).

334 Analysis of malaria vectors

335 Preserved mosquito samples were shipped to the laboratory in Tanga for further processing and analysis. Polymerase chain reaction for identification of sibling species of the An. 336 gambiae complex and An. funestus group was conducted on a sub-sample of adult mosquito 337 selected randomly from each village. Genomic Deoxyribonecleic acid (gDNA) was extracted 338 from wings or legs of a female An. gambiae complex and An. funestus group according to 339 340 methods previously described (45). The DNA samples were used for identification of sibling species of An. gambiae complex and An. funestus group using species specific diagnostic 341 primers for An. gambiae complex (An. gambiae ss., An. arabiensis, An. quadriannulatus, An. 342

343 melas, An. merus) (46). For the sibling species of the An. funestus group, the samples were 344 identified based on species-specific primers in the internal transcribed spacer 2 (ITS2) region of the recombinant DNA (rDNA) genes, using a method previously developed to identify An. 345 346 funestus, An. vaneedeni, An. rivulorum, An. leesoni, and An. parensis (47). Genotyping results were analysed using MXPro software (Agilent technologies, Santa Clara, CA, USA). Further 347 348 analysis of malaria vector will be performed later including i) use of real time PCR (using 349 TagMan assays) to detect mutations in the knock down resistance (kdr) gene associated with pyrethroid resistance and determine the presence of kdr east and west genotypes in 350 351 An. gambiae complex (48); ii) single nucleotide polymorphisms (SNPs) genotyping to assess the population structure of mosquitoes and additional markers of insecticide resistance; 352 and, iii) Detection of P. falciparum circumsporozoite protein (Pf-CSP) and source of blood 353 354 meal (for blood fed vectors) on a sub-sample of mosquitoes (An. gambiae complex and An. funestus group) by enzyme-linked immunosorbent assay (ELISA) technique as previously 355 356 described(49).

357 Analysis of parasite population structure and molecular markers of antimalarial resistance

The samples were genotyped for parasite population structure at the University of North Carolina (USA) using molecular inversion probes (MIP) protocol as described earlier (51). The data has been used to assess the population structure and other population genetics metrics in the parasite populations from the study areas (Mosers et al. Manuscript in Preparation). The assay based on MIPs was also used to detect molecular markers of drug resistance. The analysis will focus on markers of artemisinin resistance (*P. falciparum* kelch 13, *k*-13), partner drugs particularly lumefantrine and amodiaquine (*P. falciparum* multidrug resistance –

Pfmdr1 gene) while piperaquine (Plasmepsin 2 and 3) will be assessed later. Markers of resistance to the old drugs which were previously used in Tanzania – chloroquine (chloroquine transporter gene Pfcrt) and sulphadoxine/pyrimethamine – SP (dihypteorate synthase and dihydrofolate reductase, Pfdhps and Pfdhfr genes) were also assessed. The Pfmdr1 copy number variation will be detected by real-time PCR following a previously described assay(52).

Additional analysis was done to detect the levels of *P. falciparum* Histidine rich protein 2 (HRP2) and the prevalence of *hrp2/3* gene deletion and their impacts on the performance of HRP2based mRDTs in Tanzania. Analysis of HRP2 will be done using a bead luminex assay described earlier (Rogier et al)(53), while the gene deletion will be assessed using the molecular assay that has been optimized at CDC (Bakari et al. Manuscript in Preparation). Polymorphisms in the *hrp2/3* genes was analysed by Sanger sequencing as previously described (53).

378 Human genetic analyses

Human DNA will be extracted from DBS and analysed for polymorphisms in different genes
which are known to be associated with susceptibility/ resistance to malaria. Such analyses
will target sickle cell (β-globin), a-thalasemia (α-globin), glucose 6-phosphate
dehydrogenase (G6PD) genes and others polymorphisms which will be deemed relevant.

383

384 Data management

Quantitative data was collected using tablets which were connected through internet to the 385 386 central server located at NIMR Tanga Centre. The ODK software was used to create the database and data collection applications. The data manager reviewed the data on a daily 387 basis for precision and consistency. Queries generated on a daily basis were sent back to the 388 389 head of each study team for resolution. Data cleaning and validation was done continuously and daily/weekly as well as periodic reports generated. Final cleaning was done after the 390 391 survey and analysis is being performed according to the data analysis plan which was 392 prepared at the beginning and finalized at the end of the study.

393 Qualitative data were collected using tape recorders and later the audio files were stored in 394 the computer. Audio files were transcribed from Kiswahili and translated into English 395 language. Thematic approach was used for data analysis.

396

397 Data analysis

398 The Analytical framework and modelling approaches which will be used for the study is 399 shown in figure 5.

400

The proposed analytical framework for determining the intrinsic and extrinsic drivers of malaria resilience can be derived starting from any of the five components depending on what action need to be taken or from which point of view implementation of the action targets. The model in Figure 5 illustrates the interlinks that exists between these components. Health system is assumed to affect all components, but with different magnitude and assumed to impacts more socio-anthropological and the parasitological

factors. Availability, access and utilization of malaria preventive measures is a across-cutting
component between HS, entomology and parasitology, and slightly between
anthropological aspects, with more weight given to its linkage with performance of the HS
and affects the entomological and parasitological components.

Prior to analysis, the following will be done: i) potential indicators/measures to be derived 411 412 from each component will be identified. A list with details of data to be used in calculation of 413 the indicators and what information is expected to contribute to the analytical framework will be created; ii) information from demographic/socio-economic census, available for all 414 individuals in all study villages, will be used to create a community-based vulnerability index 415 416 to malaria resilience in the study districts. The index will be build based on "who are we dealing with" -concept, i.e. the study population. A sensitivity analysis will be done to assess 417 418 how the index change when adding information from other components. Malaria prevalence levels (at finest scale possible, e.g. village/ward/district) from the parasitological 419 420 component will be used as a response to a vulnerability model. Once the preliminary step is finalized, the team will gather to refine the analytical model and to generate linkages 421 422 between components. This exercise will be used as a platform to refine set of models and approaches proposed here. 423

Different approaches are proposed to be considered for analysis. Multiple analyses are considered to accommodate different context on which drivers for malaria resilience can be studied. With that, response variable(s) will be defined from one or multiple components then use data from other components as determinants or modifiers to create associations.

All models will consider spatial differences of the study districts which will be defined usingclimate and environmental information.

The first approach will consider entomological parameters such as adult mosquito density, 430 431 their infectivity (transmission) rates, resistance and information from breeding sites (number, spread and larval density) as a response. Once mapped, these will be linked to 432 socio-demographic, socio-anthropological, parasitological and lastly HS parameters. Levels 433 434 of entomological metrics are expected to be driven by rate of utilization of preventive 435 measures, malaria infection levels, governance and institutional actions (taken by administrative team in collaboration with the HS), e.g. requesting for additional 436 interventions such as larviciding; and lastly, human activities such as type of economic 437 activity, choices on where to live/build a house, type of houses constructed, sources of 438 439 water, knowledge and burden of disease observed in the community. This model assesses 440 the problem from the vector aspects hence will derive actions focusing more on vector 441 control

The second approach will take HS as the central point of deriving the understanding on the 442 key drivers of persistence of malaria burden. Here, it is assumed that the success or failure in 443 other components depends directly on the performance of the HS or vice versa. Taking it 444 from here, a HS performance indicator will be built for all districts and modelled against 445 selected/relevant indicators from all the remaining components. One of the hypothesis here 446 could be that, if governance, institutional policies, actions and practices are not sufficiently 447 implemented, they may result into insufficient community malaria knowledge, negative 448 attitudes, high levels of entomological indicators, poor health seeking behaviours, poor 449

450 distribution and utilization of effective interventions, and finally high burden 451 (parasitological). This model is expected to derive perspectives that assess malaria stagnant 452 problem from the governance actors than the beneficiaries.

453 The last model will approach the analysis from the perspective of availability, access and utilization of malaria preventive measures. This model will try to divide the weight of the 454 455 drivers to multiple players, i.e. the HS performance, community knowledge and practices 456 and patterns of entomological parameters for example seasonality. Since the analyses will be done using the data collected at the village level, an attempt will be made to extend the 457 analysis to the entire district. Data from the health management information system (HMIS) 458 459 which is routinely collected and reported through the Demographic Health Information system 2 (DHIS2) will be used. Such data will include test positivity rates (TPR), incidence 460 461 rates, prevalence of malaria in under-fives (from MIS), school children and pregnant women using ANC data. The analyses will support development of district-wide maps of malaria 462 burden and identify key factors to be incorporated in the ongoing efforts in the micro-463 stratification of malaria. 464

465

466 **Discussion**

This protocol was used in a study that aimed at determining the reasons and factors associated with persistence of malaria in some parts of Tanzania. The regions in the northwestern and southern parts of the country were selected because they showed either increasing or unchanged malaria prevalence according to the national surveys conducted from 2007 to 2016(2,32,36). The study was implemented as a cross sectional survey and 472 covered five components which play key role in the transmission and persistence of malaria: 473 parasitological, entomological, socio-anthropological, demographic and SES, and HS. The 474 protocol was designed to perform a comprehensive and critical assessment of the possible 475 drivers of resilience of malaria in these and possibly other areas with similar transmission 476 patterns in the country.

477

478 Preliminary results show that 6,297 HHs and 28,361 individuals with median age 16yrs (IQR= 479 7-35yrs) were registered from the 16 villages. The population had similar structure among young individuals <20years but with more females compared to males particularly among 480 adult individuals. Less than half (44.1%) of the HHs had family size of >4 members and >55% of 481 the HHs owned at least one bed-net. Over 49% of individuals used bed-nets in the previous 482 night before the survey and 43.9% of HHs had bed-nets covering two members per 483 484 household. For parasitological survey, 25.8% of registered individuals (n= 7,313) were selected from 2,527 HHs (40.1%) and invited for assessment and sampling. The positivity rate 485 (PR) by mRDTs was 33.3% ranging from 21.9% to 41.1%; while by microscopy, the PR was 20.6% 486 487 and varied from 8.0% to 29.0%. Socio-anthropology interviews were conducted with a total of 1,687 heads/representatives of HHs. For qualitative surveys 32 FGDs (two from each village) and 16 488 IDIs (two per district) were conducted. Thirty-one health facilities were visited for the HS 489 490 survey; 19.4% (n=6) were hospitals; 41.9% (n=13) health centres and 38.7% (n=12) dispensaries. In the entomological survey, 8,891 adult mosquitoes were collected, whereby Anopheles 491 gambiae complex, An. funestus group and other mosquitoes accounted for 12.0%, 49.7% and 492 38.3%, respectively. 493

494 In order to successfully and timely implement study, the different components of the study 495 were strategically planned to ensure the data collected was properly linked to prevent collection of redundant information. The entire study team was divided in small teams, 496 which worked on their respective components in a way that allowed proper utilization data 497 collected by the demographic and SES team. The first team (the demographic and SES 498 499 group) conducted a census survey at least a week before other teams arrived in the study 500 area. It assigned unique identification numbers to each person in the village and individuals' data were downloaded in the electronic application that were used for data collection by 501 other teams. This was critical to ensure that all individuals assessed in the other components 502 had their information in the database that was used for the specific assessments done for all 503 sub-components of the study without a need to recollect individuals' demographics. 504

505

A comprehensive and non-traditional analysis is needed to assess the intrinsic and extrinsic 506 drivers of the observed resilience of malaria. The analytical framework to be used includes 507 the following, 1) developing a conceptual framework to establish the logical interlinks 508 between the five studied components (and their attributes); 2) applying a set of models to 509 510 learn the interlinks and determine associations with core drivers; and 3) proposing a set of indicators to be studied (this will be generated and refined during the process). The analysis 511 takes into consideration the multifaceted and complex interlinks between the five 512 components to understand these drivers while utilizing both, the quantitative and 513 qualitative information gathered during the survey. The span of outcome studied started 514 from the communities to the top of the ladder, which is the HS. The communities are the 515

516 main beneficiaries while the actors/decision makers are within the health system. There are 517 decision making processes within each of these two extreme ends which determine success 518 of interventions in place; suggesting that factors behind actions of players at community 519 level vs. health system varies. Within communities, demographic profiles and practices may be the core factors while how policies and guideline are translated into actions and 520 521 innovations of players might be core factors in the HS arm. The important hypothesis that 522 this work will use is that, there is a high variation in (almost) all core attributes even within closely located areas. The concept of "who are we dealing with here" which will be used to 523 define the participants and develop community-based vulnerability indices is essential in fine 524 scale assessments such as studying malaria hotspots. It is important to fully understand the 525 type of people, their social characteristics, decision making process, their environment, 526 527 assess subgroups within and between communities and tap what divides them, etc., then 528 relate to the outcome of interest, that makes it clear to interpret associations derived from 529 analysis.

530

The use of various models (with different outcome variable), set of hypothesis on how the components interacts and development of various indicators and metrics is expected to enrich the analysis, accurately estimate the effects and facilitate understanding of the contribution of each identified driver, their pathways and point out contextual factors. On the other side, the spatial analysis will feature out and quantify the variations in the realised associations and interlinks between main components or attributes within. That is an important finding to compliment stratification strategies. The analysis will be done for each

district, region, zone (north-western and southern) and, lastly at country level. The cascade approach of analysis is expected to determine at which point the strength of association diminishes hence inform how future implementation should be formulated. This is deemed necessary, as some of the areas within the country are potential for malaria elimination. It is intended to test how the proposed framework is useful for this analysis, refine its components during the process of analysis (with full documentation) and share the final version (with list of indicators) to other malaria stakeholders.

The current NMCP mid-term strategic plan (MSP) 2015-2020 aims at reaching pre-elimination 545 level by 2020. Furthermore, the strategic plan has the main goal of reducing the average 546 547 country prevalence to <1%. Preliminary results from the current study have shown a high prevalence of malaria in the visited areas. This reflects that the goal of reaching the 548 549 prevalence of <1% in Tanzania by 2020 and transitioning to pre-elimination may not be reached over remaining period. Various reasons may be contributing to that situation, 550 551 among them being wide transmission diversity which may have an impact on the 552 performance of NMCP in attaining its MSP goals. In response to that, during their midterm review of the MSP, NMCP introduced supplementary plan with an objective of facilitating 553 554 achievement of MSP goal by 2020. Among the revised strategies, is stratification and deploying intervention based on the local burden of malaria and making surveillance, 555 monitoring and evaluation a core intervention as recommended by WHO (54). The overall 556 557 aim is to enable NMCP to monitor progress in malaria control and produce country specific evidence-based stratification. The findings of the proposed analysis will be key in developing 558

a framework that will be routinely used by NMCP to continuously re-stratify malaria burden
using data to be generated from intensified surveillance.

Analysis and results from this study will determine factors which might be potentially 561 562 responsible for persistence of malaria and hotspots in the study areas and possibly other parts of Tanzania. The proposed triangulated analysis of the five components, rather than 563 the traditional methodology of focusing on one metric, is expected to highlight potential 564 565 drivers, their complex interactions and map spatial heterogeneity which will be an eyeopener to better understanding of determinants of malaria hotspots. This study is expected 566 to provide an important framework and data which will guide future studies and malaria 567 surveillance in Tanzania and other malaria endemic countries. The findings of the study will 568 inform the NMCP and its stakeholders on stratified and malaria targeted control 569 570 interventions required to push malaria further down to reach pre-elimination target by 2020 571 and elimination by 2030. The protocol can be modified and customized, and will be useful to other countries which might be interested in undertaking similar assessments. 572

634 **Declarations**

635 Ethical approval and consent to participate

This study obtained ethical approval from the Medical Research Coordinating Committee (MRCC) of the National Institute for Medical Research (NIMR/HQ/R.8a/Vol.IX/2551). Furthermore, permission to conduct the study in the selected regions was sought from the President's Office, Regional Administration and Local Government Authority (PO-RALG) and Regional, District and village authorities. Informed consent/assent was sought before conducting the demographic survey or including the participants into the different components of the study as well as before inserting mosquito traps into the houses.

659 Authors' contribution

DSI, MGC, CIM, SFR, FC, FF, BPM, MDS, LN, ISM, EL, YAD, BMB, RAM and FM made
substantial contributions to the conception and design of the protocol; DSI, MGC, SFR, FC,
FF, MPM and FM designed the analysis and data interpretation plan. DSI, MGC, CIM, SFR, FC,
FF, BPM, MDS, DPC, LN, ISM, EL, WHM, ADM, VB, MDS, YAD, BMB, PMH, RAM, MCM, RM,
AM, FM, RN and AM contributed in drafting and revising the protocol. All authors reviewed
and approved the final version of the manuscript.

666

667 Acknowledgments

The study team would like to thank all study participants for their contribution in the study. Special appreciation goes to the President's Office Local Government and Regional Authorities and the village, district and region authorities; particularly village Leaders, District Executive Directors (DEDs), District medical Officers (DMOs) and District Malaria Focal Persons (DMFPs) for supporting the team during the entire study period.

673 The team would also like to acknowledge the contribution of the research scientists and 674 assistants; Gasper Lugela, Francis Chambo, Tilaus Gustav, Juma Akida, Mwanaidi Mtui, 675 Caroline Minja, Maimuna Ahmed and Richard Makono from the Parasitology team. The demographic team included; Gineson Nkya, Richard Malisa, Raphael Charles, Respigi 676 677 Kiwango, Evord Kimario, Lifoba Mosoud, Stumai George, Ali Idris, Ibrahim Materego, Neema Barua, and Michael Makange. Cloud Tesha, Emmanuel Chagoha and Happyness Jeremiah 678 679 were members of the socio-anthropology team. The entomology team included Martin 680 Zuakuu, Adam Mgaya, Hashim Ally, Heri Bakari, Alex John, Neema Richard, Rukia Ahmed and Israel Msangi . The technical, administrative and logistic support rendered by the Finance 681 department at Tanga Centre (Lydia Lugomola, Derick Maira, Joseph Said and Selemani 682 Mandia) and NMCP (Abdallah Kajuna and Judith Kirama); drivers (Seth Nguhu, Francis 683 Mkongo, Saidi Maivaji, Silvester Msamila, Eliwasiri Mmbaga, Thomas Semdoe, Athumani 684 Simba and Ally Mshana) and others (Robert Mhilu, Salome Ngoda, Elfrida Mosha, Haruna 685 Mrisho, Beatrice Semng'indo and Rehema Mtibusa) is highly appreciated. 686

We are grateful to WHO through Tanzania Country Office for providing technical support. The National Institute for Medical Research is thanked for the support and providing permission to publish this protocol.
