Abstract

Purpose: This study explored the COVID-19 pandemic's impacts on domestic violence (DV) with the following research questions: 1) Did DV occurring during the pandemic differ on certain variables from cases occurring on a typical day the previous year? 2) Did DV occurring after the implementation of shelter-in-place orders differ (on these same variables) from cases occurring prior to shelter-in-place orders? **Methods**: Two logistic regression models were developed to predict DV case differences before and during the pandemic. DV reports (N=4618) were collected from the Chicago Police Department. Cases from March 2019 and March 2020 were analyzed based on multiple variables. One model was set to predict case differences since the pandemic began, and another model was set to predict case differences during the shelter-in-place period later that month. **Results**: Both models were significant with multiple significant predictors. During the pandemic period, cases with arrests were 20% less likely to have occurred, and cases at residential locations were 22% more likely to have occurred. During the shelter-in-place period, cases at residential locations were 64% more likely to have occurred, and cases with child victims were 67% less likely to have occurred. **Conclusions**: This study offers a rapid analysis of DV case differences since the pandemic and shelter-in-place began. Additional variables and data sources could improve model explanatory power. Research, policy, and practice in this area must pivot to focus on protecting children whose access to mandated reporters has decreased and moving victims out of dangerous living situations into safe spaces.

Key words: domestic violence; family violence; COVID-19; coronavirus; pandemic

When "Shelter-in-Place" Isn't Shelter That's Safe: A Rapid Analysis of Domestic Violence

Case Differences During the COVID-19 Pandemic and Stay-at-Home Orders

Purpose

Background

The COVID-19 pandemic has wreaked havoc across the world since late 2019, causing nearly 5 million individuals to fall ill and over 300,000 to die, according to the Johns Hopkins Coronavirus Resource Center as of mid-May 2020 (Dong, Du, & Gardner, 2020). COVID-19's impact on the United States (U.S.) began in late January 2020, and the numbers of individuals impacted is still rising exponentially, with a total of 1,508,291 cases and 90,340 deaths (Dong, Du, & Gardner, 2020). While research has jump-started to develop testing, treatment, and vaccines, the impact of the COVID-19 on social factors cannot be ignored. The Centers for Disease Control and Prevention (CDC) have recommended that individuals stay six feet away apart, not gather in groups, and only venture out for necessities (CDC, 2020b). As a result, businesses closed or reduced operations, schools moved online, and many individuals began working from home (CDC, 2020a). In March 2020, a number of states began issuing statewide stay-at-home or "shelter-in-place" orders further restricting their residents, including Illinois (Petrella, St. Clair, Johnson, & Pratt, 2020), which, at the time of this study, had the third largest number of COVID-19 cases of all states (Dong, Du, & Gardner, 2020). Given the unique circumstances of the COVID-19 pandemic, research is needed to identify its impacts on individuals, families, and communities.

With social distancing recommendations and shelter-in-place orders making abrupt changes to the ways people interact, this study aimed to understand the COVID-19 pandemic's potential impacts on one of the most volatile of such interactions: domestic violence. Utilizing

the U.S. Department of Justice (DOJ) definition, domestic violence includes violence toward

current or former intimate partners, family members including children, or anyone with whom

the perpetrator shares a home (U.S. DOJ, 2019). Such violence has far-reaching impacts; 1 in 3

women and 1 in 4 men in the U.S. have experienced some form of violence from an intimate

partner over the life course (Black et. al., 2011), and 68-80% of children have been exposed to

violence in the home (Jaffe, 2018). Domestic violence has devastating effects on its victims and

their loved ones, with mental health consequences and physical injuries being common; Black

and colleagues (2011) noted that women with a history of violence were nearly three times more

likely to rate their physical or mental health as poor, which may be compounded in the midst of a

global pandemic. Domestic violence can also be fatal; approximately 55% of female homicide

victims are killed by an intimate partner (CDC, 2019).

Research on domestic violence prevention and treatment is ongoing. At the time of this

study, scholars had published commentaries regarding COVID-19's potential impact on mental

health issues broadly (Kumar & Navar, 2020) and domestic violence more specifically

(Abramson, 2020; Bosman, 2020; Usher, Bhullar, Durkin, Gyamfi, & Jackson, 2020; Van Gelder

et. al., 2020). However, at this time, no known peer-reviewed studies had analyzed domestic

violence rates in light of the pandemic. With more individuals at home due to shelter-in-place

orders, violence may happen more frequently behind closed doors and in increased isolation.

Individuals may also have decreased access to resources, given that especially given that first

responders, service providers, and mandated reporters may be under reduced staffing and

increased virtual interactions (CDC, 2020a). These changes to access may be felt more acutely

by individuals in communities with strict stay-at-home orders, as in Illinois, where schools were

closed the end of the spring semester (Petrella, St. Clair, Johnson, & Pratt, 2020). During this

time of increased stress, financial strain, and fear for many (Brooks et. al., 2020), changes may then be seen in domestic violence, the factors comprising it, and the individuals experiencing it. Research is needed to understand what domestic violence looks like in this unprecedented moment, so that prevention and treatment can shift in order to appropriately respond.

Research Questions

This study analyzed the potential impacts of the COVID-19 pandemic on domestic violence reports in the U.S. through logistic regression analysis. Two models were developed to predict changes in the presentation of domestic violence before and during the pandemic at different time points, utilizing data from a large Illinois city before and during the height of key policy changes in March 2020. This study analyzed relationships between the timeframe of domestic violence occurrence and a number of key variables. This study poses the following research questions:

1. Will domestic violence that occurred during the COVID-19 pandemic in March 2020 have key differences in the presence of a sex offense, weapon use, resulting arrest, presence of child victims, and residential locationality than domestic violence occurring on a typical day in March 2019?

2. Will domestic violence that occurred after the implementation of COVID-19 shelter-in-place orders on March 21, 2020 have key differences in these same variables than domestic violence occurring during the pandemic but prior to shelter-in-place orders?

Methods

Sampling

The study's sample is comprised of police reports from the Chicago Police Department (CPD). Reports on cases that occurred during the months of March 2019 and March 2020 were

utilized. Data was downloaded from the Chicago Data Portal (2020). March 2019 was used as a "usual circumstances" comparison to the March 2020 calls, which occurred toward the beginning of the COVID-19 pandemic hitting this city. March 2020 is also the month in which the first shelter-in-place order was put into effect (Petrella, St. Clair, Johnson, & Pratt, 2020), which became a point of analysis.

There were 19,747 police reports documented by CPD for March 2019 cases, and there were 15,852 reports for March 2020 cases. The data was then narrowed to any reports considered domestic incidents, for a total of 6,560 reports. Data was then imported from a CSV file into a Stata data file. The sample was then reduced only to reports involving some kind of physical or sexual violence toward a person. These offenses included any kind of assault, any kind of battery, homicide, criminal sexual assault, and any sex offense against adults, as well as physical or sexual offenses against children. (Arson, damage to property, trespassing, "deceptive practices" such as identity theft, any kind of robbery or theft, and weapons violations were excluded. Stalking, kidnapping, verbal harassment, and violations of orders of protection were not included, as these could not be confirmed to have a component of physical or sexual violence.) The final sample consisted of 4,618 police reports. This dataset did not include any demographic information about victims or perpetrators; information was limited to basic case descriptors, its crime code and characteristics, location data, and basic date/time information.

Variables and Instrumentation

Two dependent variables were analyzed: occurrence of domestic violence during the pandemic or not, and occurrence of domestic violence during shelter-in-place order or not. These two dependent variables, as well as several independent variables, are described as follows:

Occurrence of domestic violence during COVID-19 pandemic. One dependent

variable for this study is whether or not a domestic violence case occurred during the COVID-19

pandemic. For this study's purposes, March 2019 and March 2020 police calls were the two

groups analyzed and represented the dummy coding for this variable, with March 2020 cases

being the group of interest and March 2019 being the reference group. This coding reflects the

study's purpose of determining whether or not there are significant differences in the

composition of domestic violence cases before and during the COVID-19 pandemic. To create

this variable, any report for domestic violence happening between March 1-31, 2020, was coded

as "pandemic" = "1." Any report for domestic violence happening between March 1-31, 2019,

was coded as "pandemic" = "0."

Occurrence of domestic violence during shelter-in-place order. The other dependent

variable for this study is whether or not a domestic violence case occurring during the pandemic

happened before or after the shelter-in-place order for the city of Chicago took effect, as this

order placed additional constraints on individual's interactions and whereabouts. The shelter-in-

place, or "stay at home" order went into effect on March 21, 2020, at 5:00pm (Petrella, St. Clair,

Johnson, & Pratt, 2020). Cases occurring on or after this time were the group of interest, and

cases between March 1, 2020 and the time of the shelter-in-place order on March 21, 2020,

comprised the reference group. This coding reflects the study's purpose of determining whether

or not there are significant differences in the composition of domestic violence cases before and

during shelter-in-place. To create this variable, any report for domestic violence happening

between March 21 at 5:00pm and March 31 at 11:59pm, was coded as "stayhome" = "1." Any

report for domestic violence happening between March 1 at 12:00am and March 21 at 4:59pm

was coded as "stayhome" = "0."

Presence of sex crime. The presence of a sex crime during domestic violence cases was

one independent variable analyzed. For the purposes of this research, sex crime was

operationalized as any of the following crimes: criminal sexual assault, sex offense, and any

sexual offenses against children. A variable called "sexcrime" was created, and any case

containing one of these elements was coded as "1," and any case that did not contain a sex crime

was coded as "0."

Use of weapon. The use of a weapon during domestic violence cases was another

independent variable contributing to these analyses. In CPD records, all cases involving weapons

were designated as "aggravated" per the criminal code. A variable called "weapon" was created,

and any case involving the use of a weapon was coded as "1," and any case that did not was

coded as "0."

Whether or not arrest was made. The issuance of an arrest during domestic violence

cases was another independent variable contributing to these analyses. In CPD records, all cases

in which an arrest was made were coded as such. A variable called "arrest" was created, and any

case in which an arrest was made was coded as "1," and any case without was coded as "0."

Presence of child victim(s). The presence of one or more child victims during domestic

violence cases was another independent variable contributing to these analyses. In CPD records,

cases involving children were categorized as "offenses against children." A few crimes (n=7) in

which child victims were referenced in descriptions, but not categorized under "offenses against

children," were manually recoded under this category. A variable called "child" was created, and

any case involving a child victim was coded as "1." All cases without reported child victims

were coded as "0." An interaction term was also created between presence of child victims and

presence of sex crimes.

Location of offense. A final independent variable was location, or more specifically,

whether or not the violence took place at someone's residence. For the purposes of this research, residence was operationalized as any of the following locations: apartment, residence, nursing home facility, or the grounds, parking lot, or yard of any of these locations. Hotels were not included as residences, nor were any commercial locations or outside spaces unattached to a place where someone lived. A variable called "residence" was located, and any case taking place at one of these residences was coded as "1." All cases taking place elsewhere were coded as "0."

Data Analysis Plan and Rationale

Logistic regression analysis was chosen as the primary data analysis tool for this study, as a number of independent variables were of interest, thus justifying the need for a multivariate analysis. Utilizing a maximum likelihood estimator, logistic regression analysis selects coefficients that maximize the probability of reproducing the sample data. Since two "whether or not" situations are being examined, it makes sense to analyze them in terms of probabilities or likelihood of each event occurring. The study offers two models with dichotomous dependent variables: one predicts whether or not a domestic violence case took place during the COVID-19 pandemic, and the other predicts whether or not a domestic violence case took place after the shelter-in-place order went into effect. The size of this sample is much greater than the minimum needed for logistic regression (anywhere from 100-500 observations; Long, 1997). In addition to ensuring independence of observations and proper sample size, multicollinearity and influential data checks were performed to ensure these assumptions of logistic regression were met. Each model utilized in the study and their formal specifications are outlined as follows.

Model 1: Occurrence of domestic violence during COVID-19, regressed on multiple variables. The first logistic regression model features occurrence of domestic violence before or during the COVID-19 pandemic regressed on the following independent variables: presence of a

sex crime, weapon use, resulting arrest, presence of child victim(s), and residential locationality.

Under this model, it is expected that, all other things being equal: when a sex crime is present,

probability of domestic violence occurring during the COVID-19 pandemic changes; when a

weapon is used, probability of domestic violence occurring during this pandemic changes; when

an arrest is made, probability of domestic violence occurring during this pandemic changes;

when a child victim is present, probability of domestic violence occurring during this pandemic

changes; and when the location of the violence is a residence, probability of domestic violence

occurring during this pandemic changes. The intercept in this model is the predicted log odds of

domestic violence's occurrence before or during the COVID-19 pandemic when there is no sex

crime present, no weapon use, no resulting arrest, no child victim(s), and the location of the

violence was not a residence. The formal model specification is as follows:

$$P(pandemic = 1) = \frac{1}{1 + e^{-(\beta_0 + \beta_1 sexcrime + \beta_2 weapon + \beta_3 arrest + \beta_4 child + \beta_5 residence)}}$$

Two-tailed significance testing was performed on each regression coefficient, and odds

ratios and their confidence intervals were reported. Two-tailed testing was chosen due to the

unprecedented nature of the COVID-19 pandemic and its yet unknown effects on domestic

violence. Given the exploratory nature of this study, this test is appropriate. Joint hypothesis

testing and interaction effects were explored based on various bivariate analyses.

Model 2: Occurrence of domestic violence during shelter-in-place order, regressed

on multiple variables. The second logistic regression model features occurrence of domestic

violence before or during the shelter-in-place order regressed on the same independent variables

as the first model: presence of a sex crime, weapon use, resulting arrest, presence of child

victim(s), and residential locationality. Under this model, it is expected that, all other things

being equal: when a sex crime is present, probability of domestic violence occurring during

shelter-in-place changes; when a weapon is used, probability of domestic violence occurring

during shelter-in-place changes; when an arrest is made, probability of domestic violence

occurring during shelter-in-place changes; when a child victim is present, probability of domestic

violence occurring during shelter-in-place changes; and when the location of the violence is a

residence, probability of domestic violence occurring during shelter-in-place changes. The

intercept in this model is the predicted log odds of domestic violence's occurrence before or

during the shelter-in-place order when there is no sex crime present, no weapon use, no resulting

arrest, no child victim(s), and the location of the violence was not a residence. The formal model

specification is below:

$$P(stayhome = 1) = \frac{1}{1 + e^{-(\beta_0 + \beta_1 sexcrime + \beta_2 weapon + \beta_3 arrest + \beta_4 child + \beta_5 residence)}}$$

Two-tailed significance testing was performed on each regression coefficient, and odds

ratios and their confidence intervals were reported. Two-tailed testing was chosen because of the

unprecedented nature of the shelter-in-place orders and their yet unknown effects on domestic

violence. Given the exploratory nature of this study, this test is appropriate. Similar to the first

model, joint hypothesis testing using the likelihood ratio test examined whether or not weapon

use and resulting arrest jointly contribute to the model fit. Also similarly, joint hypothesis testing

and interaction effects were explored based on various bivariate analyses.

Results

Descriptive Statistics

The study's dataset of March 2019 and March 2020 domestic violence cases contains

4,618 records, with complete information on sex offenses, weapon use, arrests made, child

victims, and crime locations. At this size, the sample is large enough to meet the assumptions of

logistic regression (Long, 1997). All variables are dichotomous, and independence of

observations is met. Descriptive statistics are reported for March 2019 and March 2020

separately and in aggregate (Table 1).

In terms of total domestic violence cases, 51.26% (n=2367) of the sample's cases

occurred in March 2019 and 48.74% (n=2251) took place in March 2020, meaning that the

number of total cases was slightly lower during the pandemic month than they were during the

previous year's "typical" month. During March 2020, 70.32% (n=1583) of cases took place prior

to the shelter-in-place, and 29.68% (n=668) of cases took place after. This finding is consistent

with the fact that the shelter-in-place began on March 21—just over two-thirds of the way

through the month.

In terms of overall trends, the overall sample contained cases with sex crimes 2.84% of

the time, weapon use 14.83% of the time, arrests made 20.23% of the time, child victims

involved 2.97% of the time, and residential locations involved 77.85% of the time. The amount

that these varied by occurrence before or during the COVID-19 pandemic are described in Table

1 and was explored in the multiple logistic regression analyses.

[INSERT TABLE 1]

Bivariate Analyses

Bivariate analyses were conducted on a few independent variables of interest to

determine potential need for interaction terms and joint hypothesis testing.

Several interaction effects were tested preliminarily. The most promising was the

potential interaction between the presence of a sex crime and the presence of child victims, for

both data-driven and theoretical reasons. Victims of sex crimes and child victims are two

particularly vulnerable groups whose need for in-person mandated reporting and emergency

medical resources may be particularly impacted during a pandemic and/or shelter-in-place

period, and the experience of their intersection—child sexual victimization—is prevalent

(Finkelhor, Shattuck, Turner, & Hamby, 2014). Chi-square analysis revealed a strong association

between presence of a sex crime and presence of child victims (Table 2).

Additionally, weapon use and the involvement of an arrest in domestic violence posed an

interesting relationship. Previous research has pointed to a relationship between weapon use in

domestic violence and subsequent arrest in that situation (Sorenson, 2017). Chi-square analysis

revealed a significant association between these two variables (Table 2). Joint hypothesis testing

using likelihood ratio was utilized on these two significantly associated variables, because the

size and significance of their association was smaller than the association between sex crimes

and child victims. Other bivariate relationships were analyzed, but they did not yield statistically

significant results, and thus interactions between those variables were not built into the models.

[INSERT TABLE 2]

Logistic Regression Analyses

Models were constructed for both dependent variables after several experimental runs.

Since chi-square analysis revealed a strong association between presence of a sex crime and

presence of child victims, an interaction term of these two variables was included in preliminary

runs. The interaction term was not significant for either model, so this term was dropped. Results

of each model are presented in Tables 3 and 4 and are detailed as follows.

Model 1: Occurrence of domestic violence during COVID-19, regressed on multiple

variables. The results of the first logistic regression model, predicting occurrence of domestic

violence during COVID-19 regressed on several key variables, provided interesting findings with

low explanatory value per its pseudo R^2 (Table 3).

In terms of overall model appropriateness, Hosmer-Lemeshow goodness-of-fit test

indicated that the logistic response function was appropriate with a non-significant chi-square value of 9.07, p=.97. To check for multicollinearity problems, a variance inflation factor (VIF) test was run, resulting in a low mean VIF of 1.09, indicating no problems. Influential data was assessed with Cook's distance and was not a problem for this model.

A chi-square test was then performed on the log-likelihood ratio, and because its value was greater than the critical chi-square value for a two-tailed test, df=5, the null hypothesis that all coefficients are equal to zero was rejected. In addition to the significant intercept, the variables of resulting arrest and residential location were both significant. Odds ratios were then interpreted for arrest (.804) and residential location (1.224). All other things being equal, a domestic violence case with an arrest made was thus 20% less likely (than cases without arrests) to have occurred during the COVID-19 pandemic. Similarly, all other being equal, a domestic violence case occurring at a residential location was 22% more likely (than cases at other locations) to have occurred during the pandemic. The pseudo R^2 was .004, meaning that the model only accounted for .4% of the variation in the dependent variable.

A joint hypothesis test was also conducted to determine whether or not weapon use and resulting arrest jointly contributed to the model fit. The model was run with all variables, and then run again with weapon use and arrest dropped from the model. In comparing the -2 log-likelihood between the two models and obtaining a test chi-square, a significant chi-square of 8.95, df=2, p=.01 was found, indicating that at least one of the variables tested—either weapon use, resulting arrest, or both—was significant.

[INSERT TABLE 3]

Model 2: Occurrence of domestic violence in shelter-in-place, regressed on multiple variables. The results of the second logistic regression model, predicting occurrence of domestic

violence during the shelter-in-place period regressed on several key variables, provided

additional significant findings, but again with low explanatory value pseudo R^2 (Table 4).

In terms of overall model appropriateness, Hosmer-Lemeshow goodness-of-fit test

indicated that the logistic response function was appropriate with a non-significant chi-square

value of 13.66, p=.62. To check for multicollinearity problems, a VIF test was run, resulting in a

low mean VIF of 1.05, indicating no problems. Influential data was assessed with Cook's

distance and was not a problem for this model.

A chi-square test was then performed on the log-likelihood ratio, and because its value

was greater than the critical chi-square value for a two-tailed test, df=5, the null hypothesis that

all coefficients are equal to zero was rejected. In addition to the significant intercept, in this

model, residential location was once again significant. This time, however, resulting arrest was

not at all significant, whereas the presence of a child victim was. Odds ratios were then

interpreted for residential location (1.638) and child victim (.329). All other being equal, a

domestic violence case occurring at a residential location was thus 64% more likely (than cases

at other locations) to have occurred during the shelter-in-place. Similarly, a domestic violence

case with a child victim was 67% less likely (than cases without child victims) to have occurred

during the shelter-in-place order. The pseudo R^2 was .01, meaning that the model only accounted

for 1% of the variation in the dependent variable. This was a slight improvement over the

previous model.

A joint hypothesis test was conducted once more to determine whether or not weapon use

and resulting arrest jointly contributed to the model fit. This model was run with all variables,

and then run again with weapon use and arrest dropped from the model. This time, in comparing

the -2-log-likelihood between the two models and obtaining a test chi-square, the chi-square

value was not significant at 1.95, df=2, p=.38 was found, so the null hypothesis cannot be rejected, and the conclusion is that that neither variable was significant. Weapon use and resulting arrest did not jointly contribute to this model, unlike the previous one.

[INSERT TABLE 4]

Conclusions

Interpretation of Findings

This study offers a rapid comparison of domestic violence cases occurring in a large midwestern city before and during the COVID-19 pandemic, contributing to the lack of literature in this critical area. The two models—one predicting occurrence of domestic violence during the pandemic, and the other predicting occurrence of domestic violence during the shelter-in-place period—offer multidimensionality in analyzing the pandemic's impact, taking its rapidly-changing nature in terms of impacts and regulations into account. While both models had low explanatory power (.4% and 1%, respectively), the models were statistically significant at p<.001 (model 1) and p<.01 (model 2). More important, multiple key characteristics (also significant at p<.01 or better) were identified as important predictors of how domestic violence may differ during the pandemic and under shelter-in-place orders.

Residential location was a significant predictor in both models. Location had an even greater impact during the shelter-in-place period, as residential cases were 64% more likely to have occurred during the shelter-in-place order than during the pandemic but before the order. During both periods in 2019 and 2020, cases occurring in a residential location comprised over 75% of all domestic violence cases analyzed, so this study's finding is not all that notable given the already high numbers of cases occurring in the home. However, this finding also suggests that domestic violence first responders and service providers may need to focus their efforts on

residential areas and additional methods of reaching individuals who are staying at home. This finding may also suggest that individuals in this particular area at this particular time were taking precautions and staying at home, which may suggest compliance with shelter-in-place orders.

Two other predictor variables were significant. Arrests were less likely during the pandemic, but only by 20%; this impact did not hold when shelter-in-place was ordered. What did change during shelter-in-place was the presence of child victims—by quite a margin. With cases with child victims being 67% less likely to have occurred during the shelter-in-place order, the question here may be less about occurrence and more about reporting. This finding illuminates a need for further research to understand the relationship between the COVID-19 pandemic and reporting for child victims of domestic violence, particularly around its impacts on mandated reporting numbers and access.

While a lesser focus of this analysis, one more notable finding is on the total number of reported domestic violence cases during the pandemic, as compared to the previous year. With 51.26% (n=2367) of these cases occurring before the pandemic, in this sample, police reports of domestic violence actually went down. This contradicts previously reported statistics of domestic violence increases during the COVID-19 pandemic (Bosman, 2020). While variables and case types may differ across reports, greater attention may be needed on the source of the report— police versus hotline data—than is currently being given in the public sphere.

Limitations and Strengths

This study is limited in a few key ways. A major limitation is the lack of available data. Several data sources in Chicago were searched and contacted throughout the research process, without producing anything other than administrative police data. Additionally, this data was limited in the number of variables available, and extensive and rapid data management was

needed to ready it for logistic regression analysis. Particularly concerning was the lack of

demographic information about perpetrators and victims, which limited the richness of the

analysis and the ability to understand the pandemic's impact on domestic violence for certain

communities. It is understandable that data would be sparse during this time, with reduced

staffing and competing priorities. Some data, especially confidential domestic violence

organization data, is simply not available as quickly as a pandemic would necessitate.

Additionally, there were time and methodological constraints that impacted the depth of

analysis with the data available. With more time to explore different crime codes, types of abuse

such as telephone harassment, stalking, and order of protection violations could have been

included. Finally, low pseudo R^2 results and the limitation to one metropolitan area reduce

generalizability and explanatory power of the findings, significant though they may be.

The study's strengths are the large sample, the innovation in working with available data,

and the rapidness of response. Utilizing a large city's data allowed for nearly 5,000 domestic

violence cases to be analyzed, offering great statistical power for this exploratory study. The

study was also able to adapt to available data through a rapid data management strategy that

recoded crime codes into dichotomous variables. The use of both pandemic and shelter-in-place

timeframes for analysis, with a direct comparison group to the year prior, made for a more robust

analysis and provides a glimpse at the rapid changes that data can take on during this

unprecedented time. Lastly, the study was able to make quick use of data that was available only

a month prior to analysis. Its rapid approach to analysis and writing during such limitations and

strain can serve as a model for other social work research during the COVID-19 pandemic.

Implications

This study provides a glimpse at how domestic violence may differ during the COVID-19

pandemic and its shelter-in-place orders, as well as a few key ways in which those differences manifest. Domestic violence first responders and service providers, as well as researchers, must pivot their approaches to understanding, preventing, and treating this problem given the rapidly-evolving nature of COVID-19. Given the significant findings of cases more likely to occur in residences and less likely to be reported on child victims during shelter-in-place, additional resources are needed in this critical areas, to make residential areas safer and protect children who are vulnerable at this time. The latter point is perhaps the most interesting finding of the study and one in which urgent responses may be needed. With in-person access to mandated reporters like teachers and social workers being restricted due to stay-at-home orders, innovative ways of understanding and responding to children's experiences in the home are needed to adapt to these new circumstances.

The low explanatory power of the two regression models could be improved with the identification of additional important predictors. For future research to improve, additional sources of data are needed, as are greater availability of variables that might contribute to model explanatory power. Information such as the length of wait time for police response, location of first contact with police and service providers, co-occurring protective order violations, and elements of virtual/cyber abuse would be useful to further understanding the problem. Future research could compare domestic violence reported to police, to hotlines, and both during the pandemic, compared to usual reporting rates, to determine which services individuals are accessing during this time that looks so different from the norm. Open data sharing between research and practice realms would assist in this regard.

Lastly, funding must be directed to service providers, to move victims out of dangerous living situations, where more violence is being reported, and into safe spaces. Sheltering in place

may create safety from COVID-19, which is of great public benefit. However, if physical and emotional safety are put at greater risk as a result, research and resources are needed to make sure individuals are simultaneously safe from both kinds of threats.

Note Added

Since the initial submission of this work, global case totals of COVID-19 have gone up by 800%, and global deaths have more than tripled. Given the continued seriousness of the pandemic and need for rapid data analysis, the author is delighted to see research on COVID-19 and domestic violence gain further traction in several since-published articles (Mohler et. al., 2020; Piquero et. al., 2020; Sharma & Borah, 2020; Stickle & Felson, 2020), as well as forthcoming and working papers (Bullinger, Carr, & Packham, 2020; Davis, Gilbar, & Padilla-Medina, 2020; Leslie & Wilson, 2020; Ravindran & Shah, 2020; Silverio-Murillo, Balmori de la Miyar, & Hoehn-Velasco, 2020). The author is indebted to these scholars for their important contributions in the wake of this study.

Acknowledgements

The author thanks Brett Drake, Merriah Croston, Maxine Davis, Tonya Edmond, Shenyang Guo, Melissa Jonson-Reid, and Nancy Jacquelyn Perez-Flores for their encouragement and methodological guidance. The author also thanks Amirrah Abou-Youssef, Neha Gill, Lindsay Hawley Nathan, and Andrew Houghton for their on-the-ground wisdom that motivated the continuation of this work, and for their service to the Chicago area community.
