24 Abstract

25 Background:

26 The ongoing COVID-19 pandemic caused by SARs-CoV-2 was transmitted person to person via
27 droplet infections and fecal-oral transmission. This illustrates the probability of environmentally
28 facilitated transmission, mainly the sewage.

29 Method:

30 We used existing Pakistan polio environment surveillance network to investigate presence of
31 SARs-CoV-2 using three commercially available kits and E-Gene detection published assay for
32 surety and confirmatory of positivity. A Two-phase separation method is used for sample
33 clarification and concentration. An additional high-speed centrifugation (14000Xg for 30 min)
34 step was introduced, prior RNA extraction, to increase viral RNA yield resulting a decrease in
35 *C_q* value.

36 Results:

37 A total of 78 wastewater samples collected from 38 districts across Pakistan, 74 wastewater
38 samples from existing polio environment surveillance sites, 3 from drains of COVID-19 infected
39 areas and 1 from COVID 19 quarantine center drainage, were tested for presence of SARs-CoV-
40 2. 21 wastewater samples (27%) from 13 districts turned to be positive on RT-qPCR. SARs-COV-
41 2 RNA positive samples from areas with COVID patients and COVID 19 patient quarantine
42 center drainage strengthen the findings and use of wastewater surveillance in future.
43 Furthermore, sequence data of partial ORF 1a generated from COVID 19 patient quarantine
44 center drainage sample also reinforce our findings that SARs-CoV-2 can be detected in
45 wastewater.

46 Discussion:

47 This study finding indicates that SARs-CoV-2 detection through wastewater surveillance has an
48 epidemiologic potential that can be used as early warning system to monitor viral tracking and
49 circulation in cities with lower COVID-19 disease burden or heavily populated areas where
50 door-to-door tracing may not be possible. However, attention needed on virus concentration
51 and detection assay to increase the sensitivity. Development of highly sensitive assay will be an
52 indicator for virus monitoring and to provide early warning signs.

53 Introduction:

54 Novel coronavirus pneumonia (COVID-19) caused by SARS-Cov-2 infection has become a global
55 emergency through its widespread infection with 6,189,560 confirmed cases resulting 372,469
56 deaths in 213 countries as of 1st June , 2020 (JHU 2020). In December 2019, cluster of
57 pneumonia like disease cases with symptoms including fever, difficulty in breathing, cough and
58 invasive lesion on both lungs were reported from Wuhan, China (WHO 2020a). The causative
59 agent was identified as a Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) after
60 ruling out SARS-CoV, MERS-CoV, influenza, avian influenza, adenovirus and other common
61 respiratory pathogens (WHO 2020b). Coronaviruses belonging to family *Cornaviridae* are
62 enveloped, non-segmented positive sense RNA viruses distributed in human and mammals
63 (Richman DD 2016). However, majority of human coronaviruses have mild infections but two
64 betacoronaviruses; severe acute respiratory syndrome coronavirus (SARS-CoV) and Middle East
65 respiratory syndrome coronavirus (MERS-CoV) caused outbreaks in last two decades with 10%
66 and 35.6% mortality rate respectively (de Groot et al. 2013; Hui et al. 2004; Ramadan and Shaib
67 2019).

68 . On March 11, 2020 WHO declared it as pandemic, when disease was reported in 114 countries
69 (WHO 2020c). The primary routes of viral transmission (SARS-CoV-2) was considered to be
70 through droplet infections and person to person close contact, but later it is evident from
71 various published studies that there is increasing possibility of fecal-oral transmission (Adhikari
72 et al. 2020; Cheng et al. 2004). This shows the probability of environmentally mediated
73 transmission. Since the early days of pandemic, we got interested in understanding and utilizing
74 the role of environmental sampling mainly the sewage.

75 SARS-CoV-2 resembles 82% with SARS coronavirus (SARS-CoV) which caused an outbreak in
76 2003. Studies have shown the survival of SARS-CoV in stool for up to 4 days (Hui et al. 2004).
77 Another study described the presence of SARS-CoV and its infectious nature in water and
78 sewage for days to weeks (Casanova et al. 2009). It was also described that faulty sewage
79 system contaminated with SARs-CoV in a high-rise housing estate of Hong Kong during 2003
80 was linked to SARS outbreak involving large number of residents of surrounding buildings (Peiris
81 et al. 2003). A recent study highlighted the shedding through stool of SARS-CoV-2 in cluster of 9

82 nCOVID-19 patients. It was reported that that the RNA concentration decreased from 10^7 RNA
83 copies/g to 10^3 RNA copies/g after one week of symptom onset to third week (Roman Woelfel
84 2020). Since the source of transmission of SARS-CoV-2 is still unknown therefore wastewater
85 transmission pathway can become an important mode (UNICEF 2020). Hence, the presence of
86 SARS-CoV-2 in contaminated sewage sample and its role in transmission needs to be
87 investigated. In this study, we used the existing polio environment surveillance network in
88 Pakistan through which sewage samples were collected from designated sites in different
89 districts of the country to investigate presence of poliovirus, its spread and molecular
90 epidemiology. Same samples were processed and tested for detection of SARS-CoV-2 RNA.

91 **Methods**

92 Untreated wastewater samples (sewage samples) selected for testing in this study were
93 collected using the grab sampling technique. Most of them were those collected for routine
94 polio environment surveillance (ES). Polio ES sites are either open drains or pumping stations
95 and are sampled routinely on monthly basis. Each sampling site represent 100,000 – 300,000
96 population (WHO 2015). Besides, wastewater from drains of some areas with recent history of
97 SARS-CoV2 cases were also collected for detection and re-confirmation of SARS-CoV-2
98 detection. Sampling personnel strictly followed the standard safety guidelines for personnel
99 protective equipment (PPE) required for wastewater sampling. One liter of sewage water was
100 collected from the mid-stream into a sterile, leak proof container at a downstream sampling
101 site during the peak morning flow. These samples were transported in properly sealed
102 container with information form, indicating sampling site, district, sampling date and sampling
103 time, to laboratory within 48 hours of collection maintaining reverse cold chain (WHO 2015).
104 Samples were processed in laboratory for virus concentration using the two-phase separation
105 method (WHO 2003).

106 500 ml of each raw sewage specimens was concentrated. Firstly, clarification of the sample
107 was done by pelleting of larger suspended solids by high speed centrifugation. The clarified
108 sewage sample was mixed with defined amounts of polymers, dextran and polyethylene
109 glycol (PEG). The homogenous mixture obtained by vigorous shaking is left to stand
110 overnight at 4°C in a separation funnel. The polymer helped to form two distinct layers

111 (phases) in the funnel which were collected and mixed with pellet formed in first step which
112 was then treated with chloroform (WHO 2003) and further used for extraction of RNA.

113 Before proceeding directly for RNA extraction, an additional step was introduced to increase
114 the yield of RNA, in contrast with direct processing. 400µl of processed sample was
115 centrifuged at high speed (14000Xg) for 30 min to pellet the suspended solid particles. Virus
116 may be partly bound to these solids. Supernatant was discarded carefully without disturbing
117 the pellet, which was later used for RNA extraction.

118 Spin star viral nucleic acid kit 1.0 (ADT Biotech, Phileo Damansara 1, Petaling Jaya Part No.
119 811803) was used to extract the viral RNA. Internal control provided with kits were added as an
120 amplification control in rRT-PCR. Pellet was dissolved with 430µl of lysis buffer supplied with
121 kit, followed by 5 min vortexing to homogenously dissolve the pallet. Further processing was
122 done as per the manufacturer's instructions. The final elution volume is 60µl. The extracted
123 viral RNA was store at -20°C till further testing.

124 Multiple qualitative reverse transcription real-time PCR kits for identification of SARS-CoV2
125 were used. These kits were already in use country wide for detection of SARS-CoV2 in human.
126 These were (Kit 1) Real-Time Fluorescent RT-PCR Kit for detecting 2019-nCoV by BGI China (IVD
127 &CE marked; Catalogue No. MFG030010), takes ORF 1ab gene as the target domain, (Kit 2) qRT-
128 PCR for Novel Coronavirus (2019-nCoV) Nucleic Acid Diagnostic Kit (PCR-Flourescence Probing,
129 IVD marked) by Sansure Biotech (Sansure Biotech Inc China, Ref No. S3102E). The kit utilizes
130 novel coronavirus (2019-nCoV) ORF-1 gene and a conserved coding nucleocapsid protein N-
131 gene as the target regions and finally (Kit 3) detection Kit for 2019 Novel Coronavirus RNA (PCR-
132 Fluorescence Probing) targeting the ORF 1ab and N gene of SARS-CoV-2/2019-nCoV by Da An
133 Gene Co., China (IVD and CE marked; Catalogue No. DA-930). Thermal cycling and results
134 interpretation were performed as per manufacturer's instruction.

135 For further confirmation these samples were also tested for envelop protein (E) gene detection
136 using the primers / probe sets that was published by Corman V. M. et. al. (Corman et al. 2020).
137 A 25µl reaction contain 5 µl RNA, 12.5 µl 2x reaction buffer provided with the Superscript III
138 one step RT-PCR with platinum Taq Polymerase (Invitrogen, Darmstadt, Germany; containing

139 0.4 mM of each deoxyribose triphosphates (dNTP) and 3.2 mM magnesium sulphate), 1 µl of
140 reverse transcriptase / Taq mixture from Kit and different concentration of primers and probes
141 (Table 1). Thermal cycling was carried out at 55°C for 10 min, followed by 95°C for 3min. Then
142 45 cycles of 95°C for 15 sec, 58°C for 30 sec on ABI 7500 real time system (Applied Bio Systems,
143 US. Cat # 4351104).

144 Genetic sequencing was based on conventional amplification of genomic RNA by using Qiagen
145 One step RT PCR kit as described by Shirato K et al (Shirato et al. 2020). The ORF 1a gene was
146 amplified, using a pair of primers NIID_WH-1_F501 (TTCGGATGCTCGAACTGCACC) and
147 NIID_WH-1_R913 (CTTTACCAGCACGTGCTAGAAGG). After 1st PCR, nested PCR was performed
148 using 2nd PCR primers (Sense: NIID_WH-1_F509(CTCGAACTGCACCTCATGG), Antisense:
149 NIID_WH-1_R854 CAGAAGTTGTTATCGACATAGC) and 1µl of 1st PCR product under the same
150 condition. PCR amplicons from 2nd round were purified by Qiaquick PCR purification Kit
151 (Qiagen, Germany) and directly sequenced by using Sequencing primers (Sense: NIID_WH-
152 1_Seq_F519 ACCTCATGGTCATGTTATGG, Antisense: NIID_WH-1_Seq_R840
153 GACATAGCGAGTGTATGCC) on ABI 3100 genetic analyzer using Big Dye Terminator kit
154 V.3.0.cycle sequencing kit (ABI Foster City Canada, USA). The nucleotide sequences were
155 assembled, edited and analyzed by Sequencher software v.4.9 (GeneCodes Incorporation, USA).
156 The nucleotide sequence obtained was blasted against the available NCBI databank
157 (<https://blast.ncbi.nlm.nih.gov/Blast.cgi>).

158 Results:

159 A total of 78 wastewater samples were collected between 12 to 18 epidemiological weeks from
160 38 districts across country and were tested for SARs-CoV-2 RNA. 21 wastewater samples (27%)
161 from 13 districts were positive on RT-qPCR (Table 2).

162 Primarily, 20 wastewater samples were collected during March 20, 2020 to April 09, 2020 from
163 17 districts of Pakistan; 18 samples from different polio environmental sites (ES) distributed
164 across 16 districts and 02 samples in areas with recent history of SARS-CoV2 cases from capital
165 city Islamabad. All these samples were tested against the three commercially available SARS-
166 CoV-2 RNA detection diagnostic kits (mentioned under materials and methods). Negative
167 control supplied with the diagnostic kits containing the internal control was added in each

168 sample during extraction to ensure none of the wastewater extracted RNA samples had RT-
169 qPCR inhibition. A total of 6 samples (30 %) were positive for SARs-CoV-2 RNA, out of these all
170 were detected on Kit 1, 2 (either one gene positive or both, results interpreted as per
171 manufacturer's instruction) and E gene method whereas only 4 were positive on Kit 3 (Table 2).
172 4 positive samples had *C_q* values between 32 to 38, whereas remaining 2 samples collected in
173 areas with history of SARs-CoV-2 cases from Islamabad were positive on all three diagnostic kits
174 and E gene method having *C_q* between 36 to 38 (Table 3).

175 A centrifugation step was also introduced before Viral RNA extraction to increase viral RNA
176 yield. A decrease in *C_q* value has been observed, describing an increase in viral RNA
177 concentration (Table 4). Furthermore, 56 samples collected and received in laboratory from
178 April 6, 2020 to April 28,2020 for polio diagnostics were also tested for detection of SARs-CoV-
179 2, out which 14 (24%) were positive. One sample was collected from the drain of a Rawalpindi
180 Institute of Urology (RIU), a COVID-19 patient quarantine center, while other from a drain
181 having catchment area with recent history of COVID-19 patients. Both collection sites are in
182 district Rawalpindi. These samples were found positive for SARs-COV-2 RNA on RT-qPCR.

183 The sample collected from the drain of RIU, Rawalpindi was also subjected for partial
184 sequencing of SARs-CoV-2 ORF-1a. Nucleotide sequence of partial SARs-CoV-2 ORF 1a is
185 submitted in gene bank under accession number MT539157.

186 Discussion:

187 The role of environmental surveillance in supporting Global Polio Eradication Initiative has
188 already been acknowledged (Kroiss et al. 2018). The environmental surveillance can be used as
189 supplemental tool for detection pathogens circulating within the community. Wastewater
190 provides a near-real-time data as it constantly collects feces, urine and traces of sputum that
191 can contain SARs-CoV-2 shed by the infected individuals. Viral load estimation in COVID-19
192 positive patients are still uncertain, however, recently N. Zhang *et al.* suggests levels as high as
193 600,000 viral genomes per ml of fecal material (Wu FQ 2020). Similarly another study reported
194 approximately 30,00,000 viral particles in a single fecal sample (Wu FQ 2020). A previously
195 published study on coronavirus reported that it remained infectious in water and sewage for days
196 to weeks. Researchers reported time required for 99% reduction of virus infectivity was several

197 days at room temperature in pure water or wastewater (Guangbo Qu 2020). This adds another
198 potential supplemental detection source of SARs-CoV-2 in communities.

199 In this study, we investigated the presence of SARs-CoV-2 RNA in wastewater using the existing
200 poliovirus environment surveillance network that can be used in future as an early warning
201 system for the dependent area. This definitely needs further evaluation and discussions;
202 however, this seems to have a very interesting utilization in epidemiology. A total of 21 out of
203 78 positive wastewater samples for SARs-CoV-2 RNA clearly indicates viral RNA shedding in
204 stool of infected individuals. Currently, there is no evidence of infection transmission of SARs-
205 COV-2 or related SARs-Corona via wastewater (Ahmed et al. 2020).

206 We used three commercially available kits and Published E-Gene detection assay for surety and
207 confirmatory of positivity. Analyzing table 3, samples collected from Quetta district at two
208 different time intervals indicates COVID-19 prevalence and surge in infected individuals. This
209 can be assumed from the decrease in *C_q* value in wastewater sample collected two weeks after.
210 Detection of SARs-COV-2 RNA in two specific wastewater samples collected from areas with
211 recent history of COVID-19 patients clearly explain that wastewater testing for COVID-19 can be
212 used as an early warning system. Likewise, SARs-COV-2 RNA positive samples from RIU,
213 Rawalpindi and an area in Rawalpindi with COVID patients further strengthen the findings and
214 use of this tool in future. This surveillance system can picks up vast majority of infected
215 individuals with SARs-CoV-2 who do not present symptoms for the disease (Ahmed et al. 2020).
216 Furthermore, sequence data of partial ORF 1a generated from ICT-04 also reinforce our findings
217 that SARs-CoV-2 can be detected in wastewater in Pakistan. Interestingly, the additional extra
218 centrifugation step before viral RNA extraction seems to be encouraging in increasing the yield
219 of viral RNA. This can be obvious from the data presented in table 4.

220 The surveillance through wastewater can be useful in remote or confined communities,
221 however, further studies are needed on virus concentration and detection assay to increase the
222 sensitivity. This has an epidemiologic potential for early detection of high burden area in
223 advance; and heavily populated areas where door-to-door tracing may not be possible. This
224 may also be more relevant to the developing countries with limited molecular testing.

225 Development of highly sensitive assay will be an indicator for virus monitoring and to provide
226 early warning signs.

227 Conclusion:

228 SARS-CoV-2 detection in wastewater using RT-qPCR assay, confirmed by sequencing, is a
229 milestone in the field of epidemiology. The study finding indicates that environmental
230 surveillance through wastewater could be used as early warning system to monitor viral
231 tracking and circulation in cities with lower COVID-19 disease burden or setting where person
232 to person testing is limited. The virus concentration and detection method in wastewater needs
233 attention to increase sensitivity of detection of SARS-CoV-2 in wastewater.
