## Sources of support

This work was supported by a Wellcome Trust Clinical PhD Training Fellowship [grant number 099934/Z/12/A], a strategic award from the Wellcome Trust for the MLW Clinical Research Programme and core support to the MRC Clinical Trials Unit at UCL [MC\_UU\_12023/23] [MC\_UU\_12023/26]. The Meso Scale Discovery assays were funded by Merck, Sharp and Dohme. The authors have no other conflicts of interest to declare.

Word count: 296

Background: Non-communicable diseases (NCDs) are increased amongst people living with HIV (PLWH) and are driven by persistent immune activation. The role of socioeconomic status (SES) in immune activation amongst PLWH is unknown, especially in low income sub Saharan Africa (SSA), where such impacts may be particularly severe.

Methods: We recruited Malawian adults with CD4<100 cells/ul two weeks after starting ART in the REALITY trial (NCT01825031), as well as volunteers without HIV infection. Clinical assessment, socioeconomic evaluation, blood draw for immune activation markers and carotid femoral pulse wave velocity (cfPWV) were carried out at 2 and 42 weeks post-ART initiation. Socioeconomic risk factors for immune activation and arterial stiffness were assessed using linear regression models.

Results: Of 279 PLWH, the median (IQR) age was 36 (31-43) years and 122 (44%) female. Activated CD8 T-cells increased from 70% amongst those with no education to 88% amongst those with a tertiary education ( $p=0.002$ ); and from 71% amongst those earning less than 10 USD/month to 87% amongst those earning between 100-150 USD/month ( $p=0.0001$ ). Arterial stiffness was also associated with higher SES (car ownership  $p=0.003$ , television ownership  $p=0.012$  and electricity access  $p=0.029$ ). Conversely, intermediate monocytes were higher amongst those with no education compared to a tertiary education (12.6% versus 7.3%;  $p=0.01$ ) and amongst those earning less than 10 USD/month compared to 100-150 USD/month (10.5% versus 8.0%;  $p=0.08$ ). Water kiosk use was protective against T cell activation ( $p=0.007$ ), as well as endothelial damage (MIP1 $\beta$ , sICAM1 and sVCAM1  $p=0.047$ , 0.026 and 0.031 respectively).

Conclusions: Socioeconomic risk factors for persistent inflammation amongst PLWH in SSA differ depending on the type of inflammatory pathway. Understanding these pathways and their socioeconomic drivers will help identify those at risk and target interventions for NCDs. Future studies assessing drivers of inflammation amongst PLWH should include an SES assessment.

## Key points

### What is already known?

Persistent immune activation drives an increased risk of non-communicable diseases amongst people living with HIV. The aetiology of persistent immune activation amongst PLWH is complex and includes microbial translocation, subclinical co-infection and continued low level HIV viral replication. However, the contribution of socioeconomic factors has not previously been investigated, and may be especially relevant amongst those living in low income settings.

### What are the new findings?

The contribution of socioeconomic factors to persistent inflammation differs according to the type of inflammatory pathway. PLWH with higher socioeconomic status are at increased risk of T cell activation and arterial stiffness, perhaps as a result of more sedentary lifestyles. Conversely, evidence of innate immune activation is seen amongst those with lower socioeconomic status. Water kiosk use is associated with a favourable inflammatory profile.

### What do the findings imply?

The phenotype of chronic immune activation amongst PLWH in a low-income sub-Saharan Africa setting differs according to socioeconomic status. We recommend incorporation of socioeconomic factors into future studies assessing the relationship between chronic inflammation and non-communicable diseases amongst HIV populations.

Word count: 2892

## Introduction

Non-communicable diseases (NCDs) are fast becoming the leading cause of mortality in low income sub-Saharan Africa (SSA), with DALYs related to NCDs fast approaching those from including communicable diseases<sup>1</sup>. Given the increased risk of NCDs amongst people living with HIV (PLWH) in high income countries, there is concern that the ageing HIV population will be particularly at risk from NCD related morbidity and mortality in SSA, placing further strain on already under-resourced healthcare systems. Persistent inflammation and resultant endothelial damage amongst PLWH is implicated in the pathogenesis of NCDs amongst PLWH across healthcare settings<sup>2-6</sup>. Studies to date identify several drivers of inflammation, including microbial translocation through a compromised gut mucosa, subclinical coinfection, or low level persistent HIV viraemia<sup>7-9</sup>. Aetiological mechanisms are often complex and overlapping, especially amongst those with a history of advanced immune suppression prior to treatment<sup>10</sup>.

We previously demonstrated that heightened inflammation amongst PLWH in Malawi is heterogeneous in nature, with different immunological pathways predicting different trajectories in endothelial damage during the first year of antiretroviral therapy (ART)<sup>5</sup>. In this low-income setting, the picture of persistent inflammation amongst PLWH is likely to be further impacted by socio-economic factors such as poor water and housing quality, overcrowded living conditions, low incomes and uncertain food stability leading to increased risk of gastrointestinal infections, malaria, TB, malnutrition and decreasing ability to present for routine care for acute or chronic illness<sup>11-16</sup>.

In order to modify NCD risk factors and reduce clinical burden, a multi-faceted approach involving reduction of traditional cardiovascular risk factors, pragmatic pharmacological strategies and public health messages will likely be required. Trials testing pharmacological interventions aimed at reducing inflammation amongst PLWH have so far shown modest

effects and it is not clear how current strategies could be translated to low resource settings<sup>17-19</sup>. An understanding of the extent to which socio-economic factors contribute to inflammation will strengthen the existing model of chronic inflammation in the region and help identify where interventions should be targeted to most effectively reduce non-communicable comorbidity amongst PLWH.

## Methods

ART-naïve adults with a new HIV diagnosis and CD4 <100 cells/uL were recruited prospectively from the ART clinic and voluntary HIV testing clinic at Queen Elizabeth Central Hospital, Blantyre, Malawi, (most HIV-positive patients were recruited from the REALITY trial NCT01825031), along with HIV negative adults with no evidence of infection within the previous 3 months. The enrolment visit for HIV-positive participants was 2 weeks after ART initiation to minimise visit burden in this unwell group. The cohort has been previously reported in detail <sup>4</sup>. In brief, participants underwent a detailed clinical assessment and blood draw for markers of immune activation at enrolment and 42 weeks post ART initiation. Carotid femoral pulse wave velocity (cfPWV) was also carried out at both time points as a measurement of arterial stiffness. Socio-economic evaluation was carried out using a standardised questionnaire which included domains on housing, assets, household composition, education, employment, finances, transport and health and wellbeing. All participants provided informed written consent and ethical approval was granted by the College of Medicine Research and Ethics Committee (COMREC), University of Malawi (P.09/13/1464) and the University of Liverpool Research and Ethics Committee (UoL000996). The results of the study were disseminated to the anti-retroviral clinic staff and expert patients.

### Characterisation of immune activation

Immune activation was characterised through cell surface immunophenotyping as well as quantification of plasma biomarkers of inflammation. Surface immunophenotyping of T-cells was performed on fresh PBMCs using flow cytometry <sup>4</sup>. T-cell activation, exhaustion and senescence was defined as CD38/HLADR, PD1 and CD57 expression, respectively. Monocytes were defined as classical (CD14<sup>++</sup>CD16<sup>-</sup>), intermediate (CD14<sup>++</sup>CD16<sup>+</sup>) or nonclassical (CD14<sup>+</sup>CD16<sup>+</sup>). Stored plasma was tested for 22 cytokines: Proinflammatory Panel-1 (IFN- $\gamma$ , IL-1 $\beta$ , IL-2, IL-4, IL-6, IL-8, IL-10, IL12p70, IL-13, TNF- $\alpha$ ), Vascular Injury Panel-2 (SAA, CRP, VCAM-1, ICAM-1), Chemokine Panel-1 (MIP-1 $\beta$ , IP-10, MCP-1),

Angiogenesis -Panel-1 (VEGF-A, bFGF) and single analyte assays for IL1R antagonist and IL-7, all from Meso Scale Discovery (MSD, Rockland, MD, USA). Assays were performed following the manufacturer's instructions and recommended dilutions for human plasma. Soluble CD163 was measured in plasma diluted at 1:20 using DuoSet antibodies (R&D Systems, Minneapolis, MN, USA) on MSD Multiarray plates. CMV viral loads were quantified by DNA PCR in a subset of participants with available plasma as described previously<sup>20</sup>. Values <100 copies/mL were less than 3 ct values higher than background fluorescence and were therefore considered negative.

### Statistical analysis

All socioeconomic variables were categorical and were compared by HIV status using the chi square tests. Associations were tested for socioeconomic variables and immune activation markers as well as socioeconomic variables and cfPWV within the HIV cohort. Univariate relationships were tested using Wilcoxon ranksum or Kruskal-Wallis. Socioeconomic variables showing univariate associations with immune activation markers or cfPWV at a p value<0.1 were kept for multivariate analysis by linear regression. Immune activation markers and cfPWV were log transformed for normality for linear regression analysis and back transformed for presentation of results. Regression models examining associations with socioeconomic variables were adjusted *a priori* for age and sex as confounders for immune activation markers and for age, sex, blood pressure and haemoglobin for cfPWV.

Analysis was undertaken using Stata 13.1 (StataCorp, College Station, USA).

## Results

### Clinical characteristics

Of 279 PLWH enrolled, the median age was 36 years (IQR 31–43) and 122 (44%) were female. The median (IQR) nadir CD4 count and HIV viral load were 41 cells/ $\mu$ L (18-62) and 110,000 copies/mL (4000–290,000) respectively. 110 HIV-negative participants had comparable age (median [IQR] 35 years [31–41]), with 66(60%) women. 45(16%) HIV-positive participants were diagnosed with an acute co-infection at study enrolment and CMV PCR was positive for 61 (32%) of 193 tested HIV-positive participants, with median (IQR) CMV viral load 928 copies/mL (412–3052). The median (IQR) cfPWV for the HIV-positive participants was 7.3 m/s (6.5–8.2). 15 (4%) participants died during the study.

#### Socio-economic characteristics

Socio-economic data were available for 267 participants living with HIV and 105 HIV negative participants. Overall, 212 (58%) of participants were renting or living with family and 316 (86%) used a pit latrine toilet. 201 (55%) had electricity and 95 (26%) had a private water tap at home. 75 (21%) were unemployed and of those employed, 108 (29%) earned less than 25 USD per month, although 97 (36%) of participants were not able to provide an estimate of monthly salary. 339 (92%) of participants felt that their household did not have enough food.

The main water source for participants differed according to HIV status. Comparing PLWH with participants without HIV, 105 (40%) compared to 18 (17%) used a shared domestic tap and only 59 (22%) compared to 46 (33%) used a water kiosk ( $p < 0.0001$ , table 1). There were higher proportions of participants unemployed or working in unskilled labour within the HIV cohort, who were also more likely to work 7 hours per week and longer than 8 hours per day, and tended to be on lower salaries ( $p < 0.0001$ , table 1). People living with HIV were less likely to grow crops [31 (12%) versus 32 (30%);  $p < 0.0001$ ] and experienced lower rates of food security [13 (5%) vs 16(14%);  $p < 0.0001$ ].

#### Socio-economic predictors of cfPWV amongst PLWH

On univariate analysis of the HIV positive cohort, cfPWV was higher for the 16 (8%) participants who travelled to work in a car compared to those who did not [8m/s (7.3 to 10.2) versus 7.2m/s (6.3 to 8.1);  $p=0.008$ ]; for those who owned a television [7.7 (6.7 to 8.5) versus 7.2 (6.2 to 7.8)  $p=0.0005$ ]; and for those who had an electricity supply at home [(7.4 (6.5 to 8.3) versus 7.2 (6.4 to 8.1)  $p=0.093$ ]. These factors remained predictive of cfPWV when adjusted for age, sex, blood pressure and haemoglobin: car ownership [fold change 1.3m/s (95% CI 1.10 to 1.56);  $p=0.003$ ]; television ownership [1.12m/s (1.03 to 1.23);  $p=0.012$ ]; and electricity access [1.09m/s (1.01 to 1.17);  $p=0.029$ ]. Further detail on adjusted models is reported in the supplementary data.

Socio-economic predictors of immune activation amongst PLWH

#### *Education level and income*

Amongst the HIV positive cohort, increasing education level and income were associated with increasing proportion of activated CD8 T cells (figure1). Median (IQR) proportion of activated CD8 T cells ranged from 70% (63 – 78) amongst those with no education to 88% (74 – 94) amongst those with a tertiary education ( $p=0.002$ ); and 71% (55 – 81) amongst those earning less than 10 USD/month to 87% (86 – 93) amongst those earning between 100 to 150 USD/month ( $p=0.0001$ ). Interestingly, an indirect correlation was observed with intermediate monocytes, with higher levels amongst those with no education compared to a tertiary education [12.6% (5.4 – 15.5) versus 7.3% (5.3 – 9.8);  $p=0.01$ ] and amongst those earning less than 10 USD/month compared to 100-150 USD/month [10.5% (7.8 – 15.0) versus 8.0% (5.0 – 12.9);  $p=0.08$ ].

Participants with a tertiary education tended to experience greater improvements in CD8 activation after 42 weeks of ART compared to those without any education [%change -5.8 (-16.7 to 2.2) versus 2.4 (-7.9 to 12);  $p=0.07$ ], as did those on higher incomes [% change 6.0 (-8.2 to 20.1) versus -18.2 (-21.1 to -4.8) comparing lowest and highest income categories;  $p$

value=0.0001]. However, neither educational level nor patient income predicted change in the proportion of intermediate monocytes on ART ( $p=0.69$  and  $0.41$  respectively).

Adjusting for age and sex, we first compared those with some education to those without any: IL7 was lower for those with some education [fold change  $0.20\mu\text{g/mL}$  ( $0.07$  to  $0.59$ ); $p=0.002$ ] who also trended towards lower bFGF [fold change  $0.22\mu\text{g/mL}$  ( $0.048$  to  $1.09$ ); $p=0.056$ ] and higher proportion of activated CD8 T cells [fold change  $7.02\%$  ( $-0.97$  to  $15.0$ ); $p=0.085$ ] (figures 2 and 3). Amongst those earning  $>25$  USD/month, adjusted CD8 activation and exhaustion were both higher [activation fold change  $12.7\%$  (95% CI  $7.75$  to  $17.78$ ),  $p<0.0001$ ; exhaustion  $6.77\%$  ( $1.30$  to  $12.24$ ),  $p=0.016$ ]. Levels of IL6 and IL13 were also higher amongst people with higher incomes [ $2.9\mu\text{g/mL}$  ( $1.13$  to  $7.6$ ),  $p=0.028$ ; and  $3.1\mu\text{g/mL}$  ( $1.2$  to  $8.3$ ),  $p=0.025$  respectively]. Adjusted nonclassical and intermediate monocytes were lower amongst this higher income bracket [nonclassical fold change  $-5.23$  (95%CI  $-8.94$  to  $-1.53$ ),  $p=0.006$ ; intermediate  $-1.91$  ( $-3.91$  to  $0.10$ ),  $p=0.063$ ].

#### *Household factors*

Participants with HIV who grew crops at home had higher CD8 activation [median (IQR)  $88\%$  ( $80 - 91$ ) versus  $76\%$  ( $64 - 86$ );  $p=0.0004$ ], and experienced greater improvements in CD8 activation after 42 weeks of ART [median (IQR)  $-15.8\%$  ( $-19.9$  to  $-1.9$ ) versus  $-0.18$  ( $-13.1$  to  $12.1$ );  $p=0.01$ ] over 42 weeks of ART. Baseline CD8 activation remained significantly higher amongst those who grew crops in adjusted analysis [fold change  $12.1\%$  ( $5.2$  to  $19.0$ ); $p=0.001$ ], with significantly higher adjusted levels of IL7 and IL8 [IL7 fold change  $2.47\text{pg/mL}$  (95%CI  $1.10$  to  $5.52$ ), $p=0.028$ ; IL8  $2.97\text{pg/mL}$  ( $1.10$  to  $7.97$ ), $p=0.031$ ].

Compared to those with a brick floor, participants with an earth floor had higher proportions of nonclassical monocytes at presentation [mean (IQR)  $16.9\%$  ( $9.9$  to  $25.80$ ) versus  $10.3\%$  ( $8.2 - 16.7$ );  $p=0.04$ ] and were also more likely to experience improvements after 42 weeks of ART [nonclassical monocyte mean (IQR) change  $-2.2\%$  ( $-12.0$  to  $2.9$ ) versus  $5.8\%$  ( $3.9$  to  $7.2$ );  $p=0.026$ ].

### *Water source*

Amongst PLWH using a water kiosk compared to other water sources, the median (IQR) proportion of activated CD8 T cells at baseline was lower [mean (IQR) 70% (59 to 81) versus 81% (68 to 89),  $p=0.002$ ], and decreases in CD8 T cell activation after 42 weeks of ART were less marked [-3.78 (-15.79 to 7.18) versus -9.85 (-9.80 to 20.7);  $p=0.039$ ]. Water kiosk use was also associated with lower rates of CMV PCR positivity [5(7%) versus 57(31%);  $p<0.0001$ ]. Use of a shared domestic tap was overrepresented as the main water source amongst those with CMV (shared domestic tap users compared to water kiosk; 32 (86%) versus 5 (14%);  $p<0.0001$ ). For the four PLWH who used an unprotected well as their main water source, the proportion of intermediate monocytes was higher than those who did not [median% 14.2 (95%CI 11.5 – 17.6) versus 9.3 (5.7 – 13.0),  $p=0.068$ ].

After adjustment for confounders, CD8 activation remained lower amongst water kiosk users [fold change -7.05% (95%CI -12.1 to -1.97);  $p=0.007$ ]. MIP1 $\beta$ , sICAM1 and sVCAM1 were also all significantly lower amongst kiosk users [fold change 0.63pg/mL (95%CI 0.40 to 0.99),  $p=0.047$ ; 0.65 $\mu$ g/mL (0.44 to 0.59),  $p=0.026$ ; and 0.74  $\mu$ g/mL (0.57 to 0.97),  $p=0.031$  respectively] but IL12p70 was higher [2.39 (1.34 to 4.28);  $p=0.003$ ].

## Discussion

We show that, amongst PLWH in a low income SSA setting, socioeconomic variables associate with chronic immune activation along two different inflammatory pathways. Activated CD8 T cells were expanded amongst those with variables consistent with a higher socioeconomic status including higher incomes, higher education and having home grown crops. This population was also more likely to show improvements in CD8 T cell activation on ART. Conversely CD16 positive monocytes, both non-classical and intermediate, were expanded amongst those with variables consistent with a lower socio-economic status including lower income, less education and earth flooring. This population did not shown improvements in monocyte activation on ART.

The observation that participants in higher socioeconomic groups were more likely to improve on ART has several possible explanations. Firstly, inflammation in this group may be related to HIV itself, or viral co-infection, resulting in T cell activation. Secondly, there may be an element of the ART care effect, whereby other traditional risk factors are managed once engaged in care. Lastly, although the socioeconomic variables associated with arterial stiffness (car and TV ownership, electricity connection) were not the same as those associated with T cell activation, they were consistent with a higher socio-economic status and perhaps a more sedentary lifestyle. Taken together with previous data showing that T cell exhaustion is linked with arterial stiffness during the first 3 months of anti-retroviral therapy<sup>4</sup>, there is a suggestion that there may be a relationship between T cell activation, sedentary lifestyles and increased cardiovascular risk amongst PLWH in low income SSA setting. The observation that T cell activation may be increased amongst PLWH of higher socioeconomic status has not been previously described. However, T cell activation, exhaustion and senescence have been previously linked to premature ageing and sedentary lifestyles<sup>21 22</sup>. Studies for older populations show that lower levels of physical activity predispose to a shift towards Th2 responses and T cell senescence<sup>22</sup>.

Participants in lower socio-economic groups experience expanded inflammatory monocytes, which did not improve on ART. This suggests that this aspect of innate immune activation is not linked to HIV itself or co-infections that would normally improve on ART. Subclinical TB, untreated or recurrent acute bacterial and malarial infections, or malnutrition with persistent microbial translocation could play a role. Although this association has not been previously reported amongst PLWH, there is evidence to suggest that factors associated with lower socioeconomic status are related to immune activation in other fields. In paediatrics, lower parental socioeconomic status is associated with higher levels of CRP and enhancing nutrition can improve the effects of inflammation<sup>23 24</sup>. A socioeconomic assessment of the Framingham Offspring Study showed that both higher lifetime socioeconomic status and education level predicted lower levels of inflammatory cytokines<sup>25 26</sup>. Chronic life stressors might also contribute to higher inflammation levels amongst this more economically vulnerable group<sup>27</sup>.

Water kiosk use was independently associated with lower levels of CD8 activation, inflammatory and endothelial cytokines and CMV viraemia. Water kiosk use may therefore reflect a lower infection-driven inflammatory risk profile due to improved water quality or better sanitation environments. Sima and colleagues in Jakarta showed that water kiosks produced good quality water and reduced diarrhoeal illness to a similar extent to bottled water when compared with using wells as a water source<sup>28</sup>. Shared domestic pipe use was more common among those who tested CMV PCR positive, perhaps reflecting overcrowding in urban settings leading to increased risk of close contact transmission. Intermediate monocytes were expanded amongst four PLWH who used an unprotected well as their main water source. Although this group is very small, this finding is in keeping with low socioeconomic status and unsafe water sources being associated with monocyte activation and innate inflammatory pathways<sup>29</sup>.

Study strengths include careful characterisation of socio-economic status in a longitudinal cohort study of clinically evaluated participants with and without HIV. We compare

socioeconomic data with cell surface immunophenotyping and a comprehensive panel of inflammatory biomarkers allowing a biosocial assessment of chronic inflammation among PLWH in low income SSA.

Because our cohort of PLWH all had advanced immune suppression, these findings may not be generalisable to HIV populations as a whole. Also, there may be differences in reasons for late presentation to care amongst those from higher and lower socio-economic status backgrounds such as cultural pressures or ability to take time off work. The sample size for this study may not have allowed us to identify smaller but important effects of socioeconomic variables on inflammation and arterial stiffness. Analysis of a large number of inflammatory and socio-economic markers may have led to an increase in type 1 error, and although we have presented results in keeping with an *a priori* identified biologically plausible hypothesis, it is important to note that individual mechanisms will require further characterisation in larger clinical studies.

Researchers are increasingly recognising that immune activation in PLWH is a heterogeneous process and interest is emerging around discrete clinical inflammatory phenotypes<sup>5</sup>. Here we show that socioeconomic risk factors for inflammation amongst PLWH have varied effects. Understanding the extent to which socioeconomic factors contribute to such phenotypes, especially in low income SSA, will help identify those most at risk of developing inflammation driven non-communicable disease, support policy to reduce non-communicable disease risk factors and aid efficient allocation of limited health care resources. Future studies assessing drivers of inflammation amongst PLWH should include an assessment of socioeconomic status.

## Acknowledgements

The authors would like to acknowledge the patients and their families as well as the staff in the ART clinic and Department of Medicine at Queen Elizabeth Central Hospital, Blantyre, Malawi. We would also like to acknowledge Dr Elizabeth Tilley of the Malawi Polytechnic, for support with interpreting water supply data.

We would like to thank the REALITY trial group for their support with study design and implementation.

Data Monitoring Committee: T Peto (Chair), P Musoke, J Matenga, S Phiri.

Endpoint Review Committee (independent members): H Lyall (Co-Chair), V Johnston (Co-Chair), F Fitzgerald, F Post, F Ssali, A Prendergast, A Arenas-Pinto, A Turkova, A Bamford.

## Tables

Table 1: Socio-economic variables for 367 Malawian adults according to HIV status

## Figures

Figure 1. Cell surface immune activation markers according to education and income category.

Figure 2 Adjusted fold change in cell surface immune activation markers according to socio-economic risk factors

Figure 3 Adjusted fold change in plasma inflammatory markers according to socio-economic risk factors

Legend: All inflammatory biomarkers measured in µg/mL apart from those marked \* which are in pg/mL

Figure 4. Hypothesis for the role of socio-economic determinants in chronic inflammation and endothelial damage amongst PLWH in low income SSA

Cell surface immune activation markers  
according to education status

Cell surface immune activation markers  
according to patient income

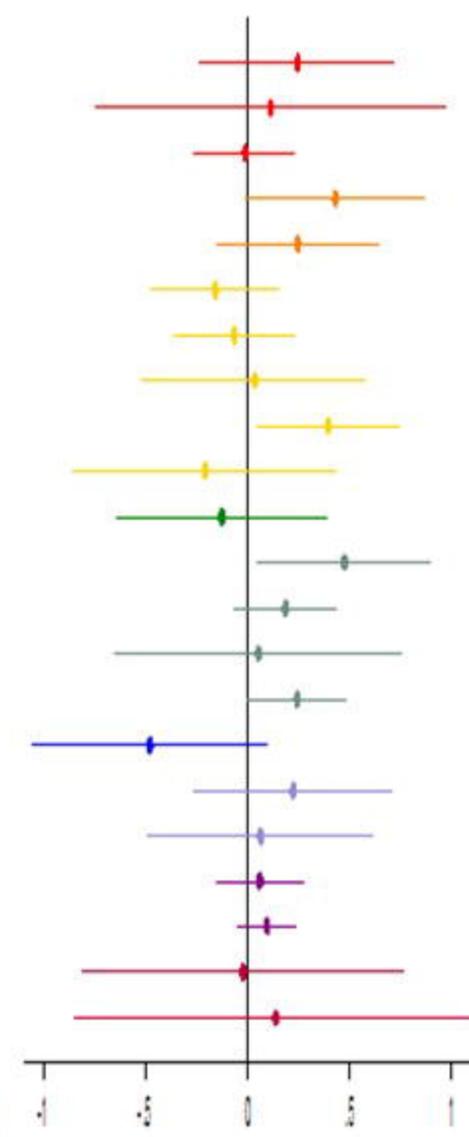

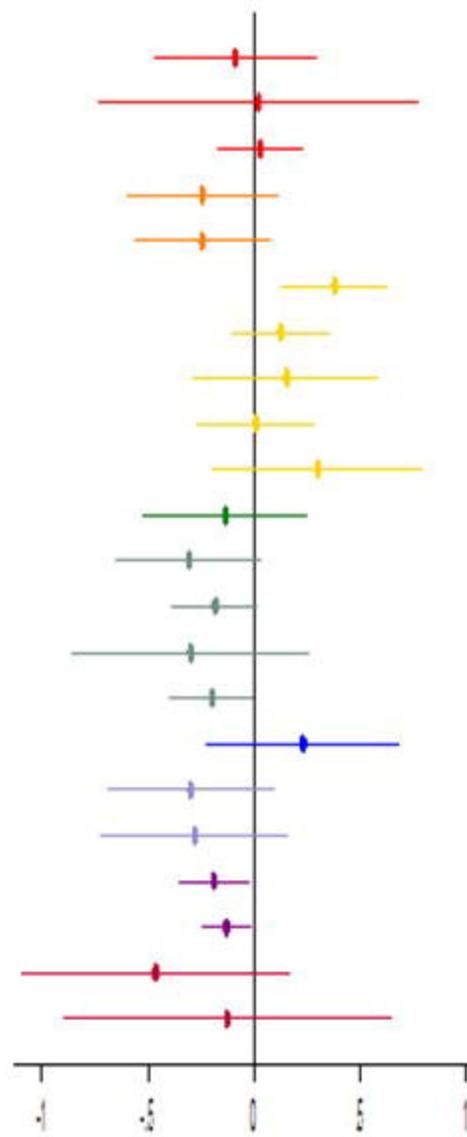

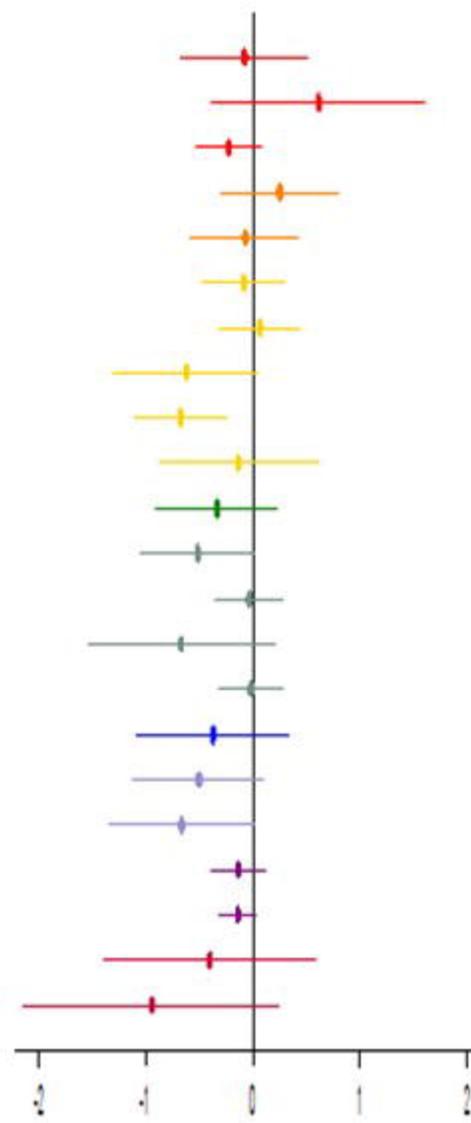

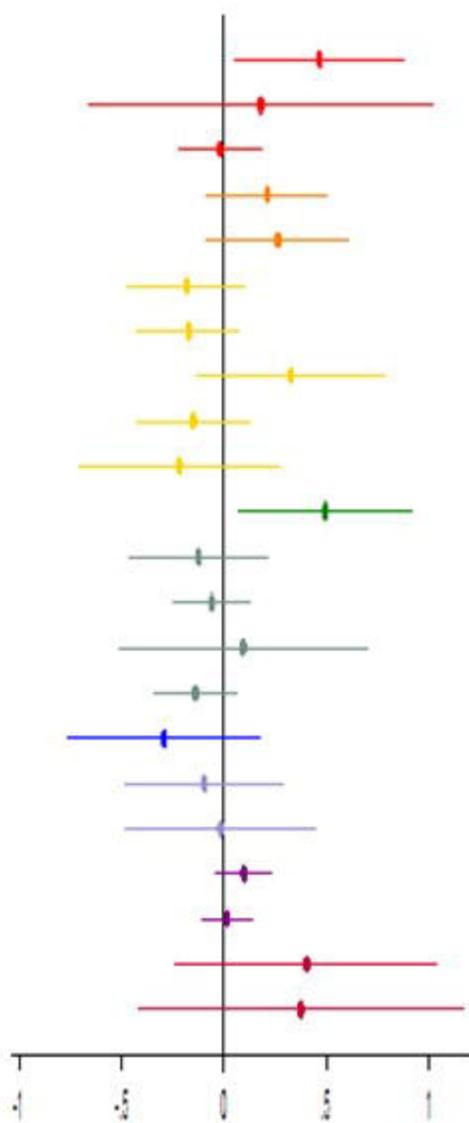

Favours Income >25 USD/month

Favours Some Education

Favours Water Kiosk as main source of water

Favours Household that Grow Crops

Pathway	Plasma Marker (pg/mL) <sup>a</sup>
Pro-inflammatory cytokines	IL6
	IL1 $\beta$
	TNF $\alpha$
Anti-inflammatory	IL10
	IL1Ra
T cell activation	IL 12p70
	IL2
	IFN $\gamma$
	IL7
	IL4
B cell activation	IL13
	IL8
Chemotaxis	MCP1
	IP10
	MIP1 $\beta$
	CD163 <sup>a</sup>
Angiogenesis	VEGF
	bFGF
Vascular inflammation	ICAM <sup>a</sup>
	VCAM <sup>a</sup>
Systemic inflammation	CRP <sup>a</sup>
	SAA <sup>a</sup>
