## 18 **Abstract**

19 A novel severe acute respiratory syndrome coronavirus (SARS-CoV-2) is the source of a  
20 current pandemic (COVID-19) with devastating consequences in public health and  
21 economic stability. Using a peptide array to map the antibody response of plasma  
22 from healing patients, we identified immunodominant linear epitopes corresponding  
23 to key proteolytic sites on the spike protein.

24

## 25 **Introduction**

26 On December 2019, a novel infectious disease causing pneumonia-like symptoms was  
27 identified in the city of Wuhan in the province of Hubei (China) [1]. This new  
28 coronavirus infectious disease (COVID-19) caused by the severe acute respiratory  
29 syndrome coronavirus-2 (SARS-CoV-2) is having a devastating impact on public health  
30 and economic stability on a global scale [2]. The World Health Organization declared it  
31 a pandemic on the 11<sup>th</sup> March 2020.

32 Mapping the epitopes corresponding to the immune system's antibody response  
33 against the virus is important for vaccine development [3, 4], diagnostic serological  
34 tests [4] as well as for identifying neutralizing antibodies with therapeutic potential [5].  
35 Indeed, epitope mapping of the SARS-CoV-1 revealed immunodominant epitopes and  
36 identified neutralizing antibodies [6-13]. However, the observation of antibody-  
37 dependent enhancement (ADE) of SARS-CoV-1 in non-human primates is concerning  
38 and should be considered for vaccine development [14, 15]. While ADE mechanisms  
39 arising from binding-only antibodies (non-neutralizing) are well documented, an ADE  
40 mechanism with neutralizing antibodies for the related MERS-CoV was also

41 reported[16]. In this case, it was shown that neutralizing antibodies targeting the  
42 receptor-binding domain (RBD) of the virus redirected viral entry to Fc-expressing cells,  
43 broadening the host-targeted cells. Thus, antibodies generated by vaccination against  
44 SARS-CoV-2 could enhance viral entry instead of offering protection, leading to  
45 vaccine-associated enhanced respiratory disease (VARED) [17].

46 The homology between SARS-CoV-1 and SARS-CoV-2 rapidly led to the hypothesis  
47 that neutralizing antibodies identified from patients in the SARS-CoV-1 in the 2003  
48 epidemic could also be neutralizing SARS-CoV-2 [18, 19]. Other antibodies with  
49 neutralizing activities have been discovered through different methodologies [20-25].  
50 The rapid propagation of SARS-CoV-2 stimulated several studies predicting the  
51 antigenic parts of the viral proteins *in silico* [26-32], and analyzing SARS-CoV-1  
52 epitopes that were conserved in this new coronavirus [33-36]. More recently, the first  
53 reports of experimental epitope mapping of the SARS-CoV-2 were deposited on  
54 repositories [37-42].

55 Herein we report the preparation of a microarray to map the antibody response to  
56 linear epitopes of the spike protein of SARS-CoV-2 and the analysis of 12 laboratory  
57 confirmed COVID-19 cases and 6 negative controls using the described peptide  
58 microarray.

59

## 60 **Materials and methods**

### 61 **Plasma specimens from COVID-19 and healthy patients.**

62 Anonymized leftovers of whole blood-EDTA were used for this method evaluation, in  
63 accordance with our institution's ethical committee and national regulations. We  
64 included 12 real-time RT-PCR confirmed COVID-19 cases hospitalized at the University

65 Hospitals of Geneva, and 6 unmatched negative blood samples from asymptomatic  
66 donors, obtained during the same period (April 2020). Analyses (see below) were  
67 performed within 72h of blood sampling without any freezing-thawing cycle.

68

### 69 **SARS-CoV-2 RT-PCR analyses and SARS-CoV-2 IgG serology**

70 As previously published [43], SARS-CoV-2 RT-PCR was performed according to  
71 manufacturers' instructions on various platforms, including BD SARS-CoV-2 reagent kit  
72 for BD Max system (Becton, Dickinson and Co, US) and Cobas 6800 SARS-CoV-2 RT-PCR  
73 (Roche, Switzerland).

74 SARS-CoV-2 IgG serology against the S1-domain of the spike protein of SARS-CoV-2 was  
75 assessed using the CE-marked Euroimmun IgG ELISA (Euroimmun AG, Lübeck,  
76 Germany # EI 2606-9601 G). EDTA-plasma was diluted at 1:101 and assessed with the  
77 IgG ELISA according to the manufacturer's instructions and has been extensively  
78 reported elsewhere [43]. Median time from RT-PCR to serology testing was 3 weeks,  
79 reason why sample were considered as healing rather than convalescent plasma. All  
80 the 12 COVID-19 samples were considered as reactive against SARS-CoV-2.

81

### 82 **Synthesis of the peptide-PNA conjugate library.**

83 The library of peptide-PNA conjugate was synthesized by automated synthesis on an  
84 Intavis peptide synthesizer as previously described [44, 45]. The synthesis was  
85 initiated with the peptide followed by the PNA tag using a capping cycle after each  
86 coupling. Hence, truncated peptides cannot hybridize on the microarray since they  
87 will not have the necessary tag. A library of 200 linear peptides was constructed based  
88 on the sequences of the spike ectodomain protein from SARS-CoV-2 (residues 1-1213-

89 Gene Bank: QHD43416.1), fragmenting the protein into two sets of 100 peptides  
90 (12mer) with an overlap of 6 residues. Each peptide-PNA conjugate was positively  
91 identified by MALDI analysis. See SI for full synthetic details and characterization data.

92

### 93 **Microarray epitope mapping.**

94 Microarrays were obtained from Agilent (Custom microarray slides, Agilent  
95 ref:0309317100-100002). Each peptide-PNA is complementary to a DNA sequence  
96 that is present 23 times at random positions on the array.

97 The arrays were incubated with plasma (1:150 dilution) for 1 hour at room  
98 temperature, washed with PBS-T and dried by centrifugation prior to the next step.

99 The arrays were then incubated with Cy-3 labeled goat anti-human IgG (ab97170 from  
100 Abcam, 1:500 dilution) for 30 min, washed with PBS-T and dried by centrifugation for  
101 scanning. See SI for detailed procedures.

102 The fluorescence intensity on the array was measured on a GenePix 4100A  
103 microarray scanner using the median value of fluorescent intensity. The data for each  
104 peptide (23 spots) was plotted as a heat map of the median value from the 23 spots.  
105 The high redundancy in the measurements and the use of a median function insures  
106 that artifacts from a microarray experiment do not contribute to the consolidated  
107 data.

108

### 109 **Validation of epitope 655-672.**

110 The peptide was synthesized according to the same protocol as for the library  
111 synthesis, replacing the PNA tag with a biotin.

112            Fluorescent bead assay: 0.3  $\mu\text{L}$  of Pierce<sup>TM</sup> High-Capacity Streptavidin Agarose  
113        Beads (catalog n°: 20357 from Thermo Scientific<sup>TM</sup>) were mixed with 50  $\mu\text{L}$  of the  
114        biotinylated peptide 10 $\mu\text{M}$  in PBS- T. The beads were incubated for 20 minutes and  
115        thereafter blocked with 200  $\mu\text{L}$  of Fetal bovine serum for 10 minutes. The beads were  
116        then washed once with 100  $\mu\text{L}$  PBS-T and 5  $\mu\text{L}$  of serum from either positive or  
117        negative patients was added together with 450  $\mu\text{L}$  of PBS-T and 50  $\mu\text{L}$  of fetal bovine  
118        serum in order to block unspecific interactions. The beads were then incubated for 90  
119        minutes and subsequently washed 4 times with 100  $\mu\text{L}$  of PBS- T in order to remove all  
120        the non-binders. Finally, 200  $\mu\text{L}$  of a 163nM solution of anti-human IgG-FITC (ab6854  
121        from Abcam) in PBS-T with 0.5% BSA was added and incubated for 1 hour. The excess  
122        of secondary antibody was washed away using 3 times 100  $\mu\text{L}$  of PBS-T and finally the  
123        beads were imaged with a Leica SP8 inverted confocal microscope.

124            By Enzyme-Linked Immunosorbent Assay (ELISA): A solution of Streptavidin (ref:  
125        S0677 from Sigma Aldrich), 100  $\mu\text{L}$  of an 80nM, in PBS was added to a Corning<sup>®</sup> 96-  
126        well Clear Flat Bottom Polystyrene High Bind Microplate (catalog n°: 9018 from  
127        Corning) and incubated overnight at 4°C. The plate was then washed three times with  
128        300  $\mu\text{L}$  of PBS-T (60 seconds, room temperature) and 200  $\mu\text{L}$  of an 800nM solution of  
129        biotinylated peptide in PBS-T was added and incubated for 90 minutes at 36°C. The  
130        plate was then blocked with 300  $\mu\text{L}$  of PBS-T with 0.5% non-fat dry milk (60 minutes at  
131        36°C). The plate was washed 3 times with 300  $\mu\text{L}$  of PBS-T (60 seconds, room  
132        temperature) and a 1:300 diluted plasma in PBS-T-0.5% non-fat dry milk was added to  
133        each well and incubated for 90 minutes at 36°C. After incubation of the plasma, the  
134        plate was washed 3 times with 300  $\mu\text{L}$  PBS-T (60 seconds, room temperature), 1 time  
135        with PBS-T 0.5% non-fat dry milk (60 minutes, 37°C) and again 3 times with 300  $\mu\text{L}$

136 PBS-T (60 seconds, room temperature). 100  $\mu$ L of Goat Anti-Human-IgG HRP  
137 conjugated (ab97175 from Abcam) 1:10000 diluted in PBS-T 0.5% BSA were added to  
138 each well and incubated for 90 minutes at 37°C. The plate was then washed 3 times  
139 with PBS-T (60 seconds, room temperature) and 200  $\mu$ L of a 0.41mM solution of  
140 3,3',5,5'-Tetramethylbenzidine (TMB) (ref: 860336 from Sigma Aldrich) in 50mM  
141  $\text{Na}_2\text{HPO}_4$ , 25mM citric acid and 0.0024%  $\text{H}_2\text{O}_2$ , pH 5.5 solution was added to the plate  
142 and incubated for 20 minutes at 37 °C. Finally, 50  $\mu$ L of a 1M sulfuric acid solution were  
143 added and the absorbance was measured at 450nm with a plate reader (SpectroMax,  
144 Molecular Device). For each sample, triplicates were performed and the fluorescence  
145 value are the average of the 3 reads.

146

#### 147 **Sequence alignment .**

148 Sequence alignment was done using Clustal Omega [46].

149

### 150 **Results and discussion**

151 SARS-CoV-2 is composed of 4 major structural proteins: S (spike), M (membrane), N  
152 (nucleocapsid) and E (envelope) [47-49]. The spike protein is responsible for entry by  
153 binding the angiotensin-converting enzyme 2 (ACE 2) on the host cell [50, 51].  
154 Accordingly, antibodies that bind the RBD and inhibit the interaction of the S protein  
155 with ACE 2 have been the center of attention. Based on the critical role of the S  
156 protein in CoV infection, we focused our work on this protein, dissecting it into two  
157 sets of overlapping linear 12mer peptides (two-fold sequence coverage with 6AA  
158 overlap between the two sets; i.e 1-12, 7-18, 13-24,...). The peptide array was  
159 prepared by hybridization of PNA-tagged peptide library onto a DNA microarray

160 (Figure 1) [52]. This technology insures a high level of homogeneity across different  
161 arrays since individual arrays are prepared from the same library hybridized onto  
162 commercial DNA microarrays. Furthermore, the arrays are designed to have each  
163 sequence present 23 times, thus insuring high accuracy by calculating the median of  
164 the observed fluorescence of the 23 spots.

165 The S protein of SARS-CoV-2 shares 76% homology with the SARS-CoV-1, [48, 53]  
166 and this homology has already been harnessed to predict epitopes based on  
167 experimental results from SARS-CoV-1. However, the different infection outcome of  
168 SARS-CoV-2 relative to SARS-CoV-1 originates in part from differences in the S protein.  
169 SARS-CoV-2 has better affinity to ACE 2 than SARS-CoV-1, yielding more efficient  
170 cellular entry [54, 55]. Furthermore, the presence of a furin cleavage site [56-58] in  
171 the S protein of SARS-CoV-2 (not present in SARS-CoV-1) coupled to an extended loop  
172 at the proteolytic site leads to higher cleavage efficacy thus facilitating its activation  
173 for membrane fusion [55, 59-61].

174 Analysis of 12 different plasma samples from SARS-CoV-2 infected patients and  
175 comparison to 6 samples from uninfected patients clearly highlighted a strong  
176 response to specific epitopes (Figure 2). The three linear epitopes most abundantly  
177 detected (SARS-CoV-2 S protein) were: 655-672, 787-822, and 1147-1158. None of  
178 these epitopes was singularly detected in all the positive samples tested, but each is  
179 detected in >40% of the positive patients. The 655-672 epitope is the most detected in  
180 positive samples and corresponds to a peptide that is not part of a secondary  
181 structures (Fig 3A-B). The corresponding epitope had been also detected in SARS-CoV-  
182 1 [8] (89% homology for the 18mer peptide, Fig 4A-C) and predicted bioinformatically  
183 for SARS-CoV-2 [27, 31, 35, 36]; however, it had yet to be observed experimentally.

184 Interestingly, this epitope is just next to the reported S1/S2 cleavage site (Fig 4A-C,  
185 furin/TMPRSS2) [50, 57]. The proteolytic cleavage of the loop 681-685 has been  
186 demonstrated to be necessary for the viral entry into the host cell [50]. Moreover, the  
187 proteolytic cleavage of the S protein could be a determinant factor for the capacity of  
188 the virus to cross species. For example, the S protein of Uganda bats MERS-like CoV is  
189 capable of binding human cells, but this is insufficient for entry [62]. However, if a  
190 protease (trypsin) is added the protein is cleaved and viral entry occurs. Furthermore,  
191 the most closely related virus to SARS-CoV-2 is RaTG-13 from a bat found in Yunnan  
192 province in 2013 which does not contain the furin cleavage sequence [49]. Taken  
193 together, this evidence suggest that cleavage of the S protein is a barrier to zoonotic  
194 coronavirus transmission. Incorporation of the furin cleavage sites could have been  
195 acquired by recombination with another virus leading to human infection. In relation  
196 to the furin cleavage site, the pathogenic avian H5N1 contains such a furin cleavage  
197 site that leads to higher pathogenicity due to the distribution of furins in multiple  
198 tissues [63]. We speculate that the binding of an antibody to the epitope 655-672  
199 would sterically block the proteolysis of S1/S2 and should thus be broadly neutralizing,  
200 since the proteolysis is required for viral entry, without promoting ADE.

201 Another epitope abundantly detected only in healing patients was the 787-822, a  
202 peptide segment extending at the periphery of the solvent exposed part of the protein  
203 (Fig 3A-B). It has also been experimentally observed in the SARS-CoV-1 [9, 13], SARS-  
204 CoV-2 [38, 39] and predicted bioinformatically [26, 27, 30, 31, 33, 36]. Interestingly,  
205 this epitope includes the S2' cleavage site of the spike protein (Fig 4D-F), which has  
206 been reported to activate the protein for membrane fusion via extensive irreversible  
207 conformational changes [53, 64]. This epitope also includes the fusion peptide (816-

208 833, Fig 4D-F) [65] which is highly conserved among coronaviruses [66, 67], suggesting  
209 a potential pan-coronavirus epitope at this location. It should be noted that a peptide-  
210 based fusion inhibitor was shown to exhibit broad inhibitory activity across multiple  
211 human CoVs [68] and that antibodies against that region have shown neutralizing  
212 activity in SARS-CoV-1 [69]. Taken together, the data support the fact that antibodies  
213 inhibiting this proteolytic cleavage should be neutralizing [61, 65].

214 Finally, the epitope 1147-1158 is found at the C terminus of the spike protein. The  
215 structural data reported thus far did not suggest a defined structure for this portion of  
216 the S protein. This epitope extends from the helix bundle 1140-1147 (Fig 3A-B) and had  
217 also been experimentally observed in SARS-CoV-1 [9] and predicted bioinformatically  
218 for SARS-CoV-2 [27, 31, 35].

219 One limitation of epitope mapping with a peptide array is that it is restricted to  
220 linear epitopes. Antibodies binding to the RBD have been shown to participate in  
221 interactions spanning multiple peptide fragments. Indeed, we did not observe a  
222 strong response to linear peptides in the RBD. A control experiment with  
223 AI334/CR3022 antibody [25, 70] showed only weak binding to 367-378 peptide  
224 sequence of the RBD.

225 To validate the results observed on the microarray, a peptide (655-672) was  
226 synthesized as a biotin conjugate for pull-down and ELISA experiments. The sequence  
227 corresponding to 655-672-biotin and a scrambled version of the biotinylated peptide  
228 were individually immobilized on agarose streptavidin beads. Beads were exposed to  
229 serum from patients that were either positive or negative for that epitope based on  
230 the microarray data and subsequently treated with anti-Human-IgG-FITC. The  
231 fluorescence of the beads was quantified by confocal microscopy (Fig 5A). As can be

232 seen in Fig 5B-E, the beads with 655-672 peptide and positive serum sample showed  
233 higher fluorescence than the ones with either negative serum or using the scrambled  
234 peptide. To further probe the binding of 655-672 peptide to antibodies of SARS-CoV-2  
235 positive patients, the same 655-672 biotinylated peptide was used in an ELISA assay  
236 (Fig 6A). Three SARS-CoV-2 positive samples showing strong 655-672 signal (Samples  
237 7, 8 and 9) and three SARS-CoV-2 negative samples (Samples 14, 15 and 17) were  
238 analyzed showing clear binding to the 655-672 peptide and not to the scrambled  
239 version (Fig 6B).

240 Next, an alanine scan was performed to assess the contribution of individual amino  
241 acids to the interaction with the antibodies of two of the COVID positive patients  
242 containing antibodies for this epitope (Sample number 1 and 6) at two different  
243 dilutions (1 to 100 and 1 to 400). For this purpose, 17 different peptide-PNA  
244 conjugates were synthesized, replacing one amino acid at the time with Ala (Fig 7A)  
245 and measuring the intensity of the observed binding on the microarray. This analysis  
246 revealed the key role of 5 residues that, if converted to Ala, lead to dramatic loss of  
247 activity (amino acids in blue, Fig 7B). Thus, the key amino acids crucial for binding with  
248 the antibodies common for these two plasma samples are H655, Y660, C662, G669 and  
249 C671. The binding of the antibody presents in sample 1 also seems to depend on the  
250 P665. The remarkable similarities between the two patients is notable considering a  
251 polyclonal response.

252

## 253 **Conclusion**

254 We have developed a peptide array for the epitope mapping of the spike protein of  
255 SARS-CoV-2. Using this array to profile healing plasma of twelve laboratory confirmed

256 COVID-19 patients and six negative controls we have discovered three  
257 immunodominant linear regions, each present in >40% of COVID-19 patient. Two of  
258 these epitopes correspond to key proteolytic sites on the spike protein (S1/S2 and the  
259 S2') which have been shown to be crucial for viral entry and play an important role in  
260 virus evolution and infection. The fact that antibodies binding to the protease  
261 cleavage sites were identified from COVID-19 patients raises the possibility that other  
262 mechanism than blocking the RBD-ACE2 interaction could be harnessed for  
263 neutralization. Furthermore, blocking proteolytic cleavage could be important to  
264 reduce antibody-dependent enhancement of viral entry, a key feature for vaccine  
265 development. Full characterization of these antibodies is necessary, and efforts on this  
266 direction are on their way.

267

Fig 2. Antibody response from 12 convalescent SARS-CoV-2 patients and 6 uninfected negative controls. A: Domains of the spike protein (SP = Signal peptide, NTD = N-terminal domain, RBD = Receptor-binding domain, FP = Fusion Peptide, IFP = internal fusion protein, HR1 = Heptad repeat 1, HR2 = Heptad repeat 2) and heat map of antibody binding to the peptide fragments (black background intensity, red 5x background intensity and yellow 10x background intensity). Sample number are indicated on the left of the heat map. B: Fluorescence intensity of antibody binding from the 12 SARS-CoV-2 positive samples (left) and 6 SARS-CoV-2 negative samples (right). The fluorescence intensities are the median of 23 values followed by normalization to the background intensity. The immunodominant regions are highlighted with the corresponding residue numbers (the epitope numbers correspond to the column on top of the dash).

Fig 7. Alanine scan by hybridization of PNA-peptide conjugates Ala-1 to Ala-17 to a DNA microarray. A) Peptide sequences of the 17 PNA-peptide conjugates used for the alanine scan, where one amino acid at the time is modified by an alanine. B) Heat map of the interaction of 655-672 positive patient plasma with the different peptides-PNA conjugates hybridized in the DNA array at two different dilutions (1 to 100 and 1 to 400). Heat map represents the normalized fluoresce average of 23 different spots in the array.
