Abstract

ISARIC (International Severe Acute Respiratory and emerging Infections Consortium) partnerships and outbreak preparedness initiatives enabled the rapid launch of standardised clinical data collection on COVID-19 in Jan 2020. Extensive global participation has resulted in a large, standardised collection of comprehensive clinical data from hundreds of sites across dozens of countries. Data are analysed regularly and reported publicly to inform patient care and public health response. This report, our 17th report, is a part of a series published over the past 2 years. Data have been entered for 800,459 individuals from 1701 partner institutions and networks across 60 countries.

The comprehensive analyses detailed in this report includes hospitalised individuals of all ages for whom data collection occurred between 30 January 2020 and up to and including 5 January 2022, AND who have laboratory-confirmed SARS-COV-2 infection or clinically diagnosed COVID-19.

For the 699,014 cases who meet eligibility criteria for this report, selected findings include:
- median age of 58 years, with an approximately equal (50/50) male:female sex distribution
- 29% of the cohort are at least 70 years of age, whereas 4% are 0-19 years of age
- the most common symptom combination in this hospitalised cohort is shortness of breath, cough, and history of fever, which has remained constant over time
- the five most common symptoms at admission were shortness of breath, cough, history of fever, fatigue/malaise, and altered consciousness/confusion, which is unchanged from the previous reports
- age-associated differences in symptoms are evident, including the frequency of altered consciousness increasing with age, and fever, respiratory and constitutional symptoms being present mostly in those 40 years and above
- 16% of patients with relevant data available were admitted at some point during their illness into an intensive care unit (ICU), which is slightly lower than previously reported (19%)
- antibiotic agents were used in 35% of patients for whom relevant data are available (669,630), a significant reduction from our previous reports (80%) which reflects a shifting proportion of data contributed by different institutions; in ICU/HDU admitted patients with data available (50,560), 91% received antibiotics
- use of corticosteroids was reported in 24% of all patients for whom data were available (677,012); in ICU/HDU admitted patients with data available (50,646), 69% received corticosteroids
- outcomes are known for 632,518 patients and the overall estimated case fatality ratio (CFR) is 23.9% (95%CI 23.8-24.1), rising to 37.1% (95%CI 36.8-37.4) for patients who were admitted to ICU/HDU, demonstrating worse outcomes in those with the most severe disease

ISARIC (International Severe Acute Respiratory and Emerging Infections Consortium)

A global federation of clinical research networks, providing a proficient, coordinated, and agile research response to outbreak-prone infectious diseases

Background

This report describes the clinical presentation, treatment and outcome of a cohort of over 800,000 patients with COVID-19 hospitalised between January 2020 and January 2022 in 60 countries. This has been possible thanks to 1701 institutions and their clinical teams contributing to ISARIC (International Severe Acute Respiratory and Emerging Infection Consortium), a grassroots collaboration https://isaric.org/.

After over 458 million cases and over 6 million deaths, COVID-19 is clearly showing us how pandemics disrupt populations by stretching healthcare systems, and shaking economies. Although clinicians and well-equipped surveillance systems can adapt to health emergencies by implementing new treatments and information systems, clinical research lacks this agility.

The advantages of an international standardised case record form. Novel diseases are, by definition, new; the scientific method is not. By developing consensus on a road map for clinical research methods before a pandemic, we are able to minimise further time defining study types, data collection tools, and potential outputs for evidence summarisation once the pathogen emerges. Using slightly adjusted standardised methods for novel diseases, evidence can be generated quickly.

While small observational studies are easy to conduct, they often record different data or may record variables in different ways. This may not allow data to be collated or findings to be compared across studies, or combined to produce a more powerful and accurate representation. In contrast, large international observational studies with a standardised form allow for international data comparisons, improved analytic control of confounders, and therefore enable the acquisition of high levels of evidence.

How we got here with ISARIC. In 2013, ISARIC and the World Health Organisation (WHO) implemented the standardised Clinical Characterisation Protocol to evolve clinical data into research evidence during health emergencies.

In January 2020, we launched our case report form when only 846 COVID-19 cases had been reported globally. The first patient was enrolled on 30 January 2020. Today, our partners have collected standardised, in-hospital clinical data from over 800,000 patients, in 1701 sites, across 60 countries. More than half of these patients live in low- and middle-income countries. This partner-fueled initiative is to our knowledge the largest COVID-19 in-hospital international database in the world.

In this report, we present the current state of our database, which all our collaborators can access by submitting a statistical analysis plan to our clinical team. We encourage our collaborators to test their research hypothesis within the framework of ISARIC's collaborative Partner Analysis scheme [2]. The majority of this database is additionally available to external researchers via application to our Data Access Committee at https://www.iddo.org/covid19/data-sharing/accessing-data.

These analyses are available on the ISARIC COVID-19 Dashboard at https://livedataoxford.shinyapps.io/CovidClinicalDataDashboard/

To contribute, please contact ncov@isaric.org.

Methods

The results in this report are produced using data from the ISARIC COVID-19 database of international, prospective observational data on clinical features of patients admitted to hospital with COVID-19. Data collection was structured on the ISARIC/WHO Clinical Characterisation Protocol for Severe Emerging Infections, a standardized protocol for investigation of severe acute infections by pathogens of public health interest [3] and the ISARIC case report forms [4] designed for standardized data collection from the start of an outbreak and rapid dissemination of clinical information [5-9]. Data are collected on Research electronic Data Capture (REDCap, version 8.11.11, Vanderbilt University, Nashville, Tenn.), hosted by the University of Oxford. Additional data, collected using a wide variety of data systems, are submitted by international investigators who are not using the University of Oxford REDCap instance. Data are curated by the Infectious Diseases Data Observatory [10] to the CDISC Study Data Tabulation Model (SDTM) for harmonised analysis [11].

SDTM formatted data are processed in R 4.1.0 [12]. Initial data cleaning includes custom scripts designed to identify results of laboratory SARS-CoV-2 testing, and to standardise nomenclature for comorbidities, symptoms at admission, treatments, and outcomes.

Patients are excluded if they did not have laboratory or clinically confirmed SARS-CoV-2 infection. Patients are considered to be lost to follow up if either a) they were transferred to another facility, or b) they had an unknown outcome and the last date upon which any data was recorded for them was 45 days or before the date of data extraction. Patients with unknown outcome where the last recorded data was less than 45 days old are instead categorised as receiving ongoing care.

Comorbidities, symptoms at admission, and treatments (in both the full population and the intensive care unit (ICU)/high dependency unit (HDU) population) are included in the report only if at least 10% of patients have their presence or absence recorded. Laboratory and vital sign measurements that fall within the top 2.5% and bottom 2.5% of values, within both the <10 year age group and the ≥ 10 year age group, are taken to be likely mis-entered and changed to missing for this report. Similarly, variables for time durations are converted to missing if their values are either negative or in the top 2.5% of values. Dates are converted to missing where they are before the 1st January 2020 (except for dates of birth and hospital admission) or after the date of data extraction.

The following COVID-19 symptom definitions were used:

- WHO:
  1. A combination of acute fever and cough,
  Or
  2. A combination of three or more of: fever, cough, general weakness and fatigue, headache, myalgia (we used muscle aches, joint pain), sore throat, coryza (we used runny nose), dyspnoea (we used shortness of breath), anorexia, nausea and vomiting, diarrhoea, altered mental status (we used altered consciousness or confusion)

- Centers for Disease Control (CDC), United States:
  1. At least two of: fever, chills (not available), rigors (not available), myalgia, headache, sore throat,

new olfactory and taste disorder,
Or
2. At least one of: cough, shortness of breath, difficulty breathing (not available)

- Public Health England
  New cough (we used cough), or temperature $\geq$ 37.8°C (we used history of fever), or a loss or change in sense of smell or taste

- European Centre for Disease Prevention and Control
  At least one of: cough, fever, shortness of breath, sudden onset anosmia, ageusia or dysgeusia

Data manipulation is performed using the tidyverse collection of packages [13], as well as ff [14] and dtplyr [15]. Data visualisation makes use of ggplot [16] and its extension ggupset [17]. The report is generated using knitr [18].

This report only includes individuals for whom data collection commenced on or before 05 January 2022.

Results

The flow chart (Figure 1) gives an overview of the cohort and outcomes as of 05 January 2022.

Figure 1: Overview of cohort and outcomes as of 05 January 2022.

Data have been contributed by 1701 sites in 60 countries (see Figure 2). 470876 (58.8%) of the patients are from low- and middle-income and 329579 (41.2%) from high-income countries. The two largest contributors to the database are South Africa (54%) and the UK (34.1%). Plots grouped by regions and calendar time are shown in Figure 3 and 4. The cohort satisfying the inclusion criteria has **699014** cases.

Figure 2: Distribution of patients by country

Figure 3: Distribution of patients by world bank region and country

Figure 4: Distribution of patients by world bank region and time

Demographics

Of these 699014 cases, 344372 (49.3%) are males and 353789 (50.6%) are females. Sex is unreported for 853 cases. The median age is 58 years, ranging from 0 to 119 years. One-third of the patients are 70 years old and above. Demographics, including age, sex, and outcome, are presented in Table 1 and Figure 5.

Table 1: Patient Characteristics. Proportions are presented in parentheses, and have been rounded to two decimal places.

Variable	Count (proportion)
Size of cohort	699014
By sex	
Female	353789 (0.51)
Male	344372 (0.49)
Unknown	853 (0)
By outcome status	
Death	151468 (0.22)
Discharge	481050 (0.69)
LTFU	66272 (0.09)
Ongoing care	224 (0)
By age group	
0-9	15522 (0.02)
10-19	15635 (0.02)
20-29	42947 (0.06)
30-39	76545 (0.11)
40-49	92948 (0.13)
50-59	127055 (0.18)
60-69	119445 (0.17)
70+	200120 (0.29)

Presenting symptoms

The observed mean number of days from (first) symptom onset to hospital admission was 3, with a standard deviation (SD) of 4.1 days and a median of 1 days.

A detailed analysis of patients' symptoms has been reported in a previous publication [19]. The prevalence of symptoms on admission to the hospital is summarised in Table 3 and Figure 6a. (Note that South Africa did not collect symptoms data. The overall frequency of missing data outside South Africa is 11%). The five most common symptoms at admission are shortness of breath, cough, history of fever, fatigue/malaise, and altered consciousness/confusion, accounting for 60.8%, 58.5%, 56.7%, 38.6%, 18.6% of patients with at least one symptom recorded.

Clusters of symptoms are presented in Figure 6b and 6c. The most common symptom combination is shortness of breath, cough, and history of fever.

Figure 5: Age and sex distribution of patients. Bar fills are outcome (death/discharge/lost to follow-up (LTFU)) at the time of report.

Table 2: Outcome by age and sex. Proportions are calculated using the row total as the denominator.

Variable	Death	Discharge	LTFU	Case fatality ratio
Age				
0-9	402 (0.03)	14083 (0.91)	1037 (0.07)	0.03
10-19	409 (0.03)	14020 (0.9)	1205 (0.08)	0.03
20-29	1792 (0.04)	37613 (0.88)	3536 (0.08)	0.05
30-39	5731 (0.07)	64820 (0.85)	5960 (0.08)	0.08
40-49	11836 (0.13)	73626 (0.79)	7439 (0.08)	0.14
50-59	24441 (0.19)	92161 (0.73)	10389 (0.08)	0.21
60-69	33849 (0.28)	74304 (0.62)	11246 (0.09)	0.31
70+	72116 (0.36)	106947 (0.53)	21031 (0.11)	0.4
Sex				
Female	70171 (0.2)	252838 (0.71)	30674 (0.09)	0.22
Male	81144 (0.24)	227773 (0.66)	35337 (0.1)	0.26

Figure 6: Clinical symptoms of patients at admission

(a) Frequency of symptoms seen at admission amongst COVID-19 patients. Bars are annotated with a fraction representing the number of patients presenting with this symptom over the number of patients for whom presence or absence of this symptom was recorded.

Table 3: Prevalence of symptoms.

Symptoms	Present	Absent	Unknown
Shortness of breath	144715 (0.21)	93459 (0.13)	460840 (0.66)
Cough	138763 (0.2)	98568 (0.14)	461683 (0.66)
History of fever	134261 (0.19)	102491 (0.15)	462262 (0.66)
Fatigue/malaise	83497 (0.12)	132899 (0.19)	482618 (0.69)
Altered consciousness/confusion	40916 (0.06)	178725 (0.26)	479373 (0.69)
Vomiting/nausea	37948 (0.05)	185823 (0.27)	475243 (0.68)
Muscle aches joint pain	36370 (0.05)	171699 (0.25)	490945 (0.7)
Diarrhoea	35616 (0.05)	188417 (0.27)	474981 (0.68)
Chest pain	29417 (0.04)	191338 (0.27)	478259 (0.68)

Lost/altered sense of smell	11545 (0.02)	161067 (0.23)	526402 (0.75)
Asymptomatic	9960 (0.01)	130118 (0.19)	558936 (0.8)
Runny nose	6329 (0.01)	195563 (0.28)	497122 (0.71)
Skin rash	4888 (0.01)	207175 (0.3)	486951 (0.7)
Bleeding	3889 (0.01)	213995 (0.31)	481130 (0.69)
Seizures	2382 (0)	210896 (0.3)	485736 (0.69)
Lymphadenopathy	948 (0)	200910 (0.29)	497156 (0.71)
Conjunctivitis	761 (0)	207855 (0.3)	490398 (0.7)
Ear pain	647 (0)	175724 (0.25)	522643 (0.75)

(b) The distribution of combinations of the five most common symptoms, amongst all patients for whom these data were recorded. Filled and empty circles below the x-axis indicate the presence or absence of each comorbidity.

The observed symptoms on admission partly represent case definitions and policies for hospital admission, which may change as time passes. The overall percentages of patients meeting the four most common case definitions were 77%, 84%, 77%, 61% for CDC, ECDC, PHE, and WHO, respectively, and varies by age (Figure 7).

(c) Heatmap for correlation between symptoms. Fill colour is the phi correlation coefficient for each pair of symptoms, calculated amongst patients with recorded presence or absence of both.

The frequency of presenting symptoms varies with age (Figure 8). Altered consciousness increases with age. The proportions of fever, respiratory and constitutional symptoms are higher in patients aged 40-60. Cough or fever were also common in children aged 0-9. The proportion of abdominal pain, diarrhoea, and vomiting are less age-dependent and similar across age groups.

Figure 7: Proportion of patients that meet the 4 most common COVID-19 symptom case definitions by age

Figure 8: Symptoms recorded at hospital presentation stratified by age group. Boxes show the proportion of individuals with each symptom. The size of each box is proportional to the number of individuals represented. N is the number of individuals included in the plot (this varies between plots due to data completeness. The numbers for panel c, e, f, i were patients who had informaton on at least one symptom).

In Figure 9, we present the frequencies of most common symptoms varied by regions. Each panel corresponds to a different region, and within region, symptoms that were present more often correspond to higher y-axis coordinates. To improve visualization, transparency decreases with increasing frequency. Across all geographical regions, shortness of breath, fever, and cough are the three symptoms with the highest prevalence.

Figure 9: Symptoms recorded at hospital presentation stratified by region. The numbers next to each bar represent patients presented with this symptom/patients recorded. The N in the title represents the total number of patients in each region, including those with or without symptoms recorded.

Table 4: Prevalence of comorbidities.

Comorbidities	Present	Absent	Unknown
Hypertension	210890 (0.3)	320592 (0.46)	167532 (0.24)
Diabetes	143120 (0.2)	404646 (0.58)	151248 (0.22)
Chronic cardiac disease	71819 (0.1)	463113 (0.66)	164082 (0.23)
Smoking	66149 (0.09)	139210 (0.2)	493655 (0.71)
Obesity	48608 (0.07)	263053 (0.38)	387353 (0.55)
Asthma	47285 (0.07)	487761 (0.7)	163968 (0.23)
Chronic pulmonary disease	46780 (0.07)	485758 (0.69)	166476 (0.24)
Chronic kidney disease	41862 (0.06)	486467 (0.7)	170685 (0.24)
HIV/AIDS	26813 (0.04)	496784 (0.71)	175417 (0.25)

Pregnancy	18773 (0.03)	252612 (0.36)	82593 (0.12)
Other	14849 (0.02)	435251 (0.62)	248914 (0.36)
Tuberculosis	11392 (0.02)	317078 (0.45)	370544 (0.53)
Chronic haematological disease	9236 (0.01)	234589 (0.34)	455189 (0.65)
Liver disease	8003 (0.01)	252552 (0.36)	438459 (0.63)
Malnutrition	4797 (0.01)	226291 (0.32)	467926 (0.67)
Immunosuppression	4536 (0.01)	119491 (0.17)	574987 (0.82)
Transplantation	1640 (0)	122729 (0.18)	574645 (0.82)
Rare diseases and inborn errors of metabolism	641 (0)	123016 (0.18)	575357 (0.82)

Comorbidities and other concomitant conditions at admission

Information is available on at least 75% of cases for diabetes, chronic pulmonary disease, chronic kidney disease, asthma, malignant neoplasm, cardiac chronic disease, HIV/AIDS, and hypertension (Table 4). Conditions present in at least 10% of cases are hypertension (30% of those reported), diabetes (20%), chronic cardiac disease (10%) (Figure 10a). Combinations of the five most prevalent conditions are presented in Figure 10b.

Figure 10: Comorbidities and other concomitant conditions

(a) Frequency of comorbidities or other concomitant conditions seen at admission amongst COVID-19 patients. Bars are annotated with a fraction representing the number of patients presenting with this comorbidity over the number of patients for whom presence or absence of this comorbidity was recorded.

(b) The distribution of combinations of the five most common such conditions, amongst all patients for whom these data were recorded. Filled and empty circles below the x-axis indicate the presence or absence of each comorbidity.

The age distribution of the most frequent concomitant conditions is presented in Figure 11. Dementia and hypertension increase with age.

Figure 11: Comorbidities recorded at hospital presentation stratified by age group. Boxes show the proportion of individuals with each symptom. The size of each box is proportional to the number of individuals represented. N is the number of individuals included in the plot (this varies between plots due to data completeness).

In Figure 12, the frequencies of most common comorbidities in patients by regions. Each panel corresponds to a different region, and within region, more frequent comorbidities correspond to higher y-axis coordinates. To improve visualization, transparency decreases with increasing frequency. The most common comorbidities are hypertension, diabetes, obesity, chronic cardiac disease, smoking, which are similar across regions.

Figure 12: Comorbidities recorded at hospital presentation stratified by region. The numbers next to each bar represent patients presented with this symptom/patients recorded. The N in the title represents the total number of patients in each region, including those with or without symptoms recorded.

Vital signs

Oxygen saturation was recorded for 229816 patients at admission. Of these, 34.4% were on oxygen therapy, and 65.6% were not. At admission, the median oxygen saturation of those who were on oxygen therapy was 95%, whereas the median was 96% for those who were not on oxygen therapy (Figure 13 provides a breakdown of oxygen saturation by age and oxygen therapy status). Among those who were on oxygen therapy at admission (N = 79059), 34.9% had oxygen saturation <94, and among those who were not on oxygen therapy at admission (N = 150757), 25.6% had oxygen saturation <94. All vital signs are presented in Figure 13 by age.

Figure 10: Box and whisker plots for observations at hospital presentation stratified by age group. N is the number of individuals included in the plot (this varies between plots due to data completeness).

Laboratory values

Laboratory tests results are available for a minority of patients. They are summarised in Figure 14.

Figure 11: Box and whisker plots for laboratory results within 24 hours of hospital presentation stratified by age group. N is the number of individuals included in the plot (this varies between plots due to data completeness).

(a) Alanine transaminase (ALT)

(b) Aspartate transaminase (AST)

(c) Bilirubin

(d) Protrombin time

(e) Urea

(f) White blood cell count (WCC)

(g) Neutrophils   (h) Lymphocytes

(i) C-reactive protein (CRP)

Treatment

Antibiotics were given to 247929/669630 (37%) patients, and 62541/665930 (9.4%) received antivirals. These treatment categories are not mutually exclusive since some patients receive multiple treatments - the denominators differ due to data completeness. Of 608474 patients with data available on oxygen supplementation within 24 hours from admission, 185062 (30.4%) received supplemental oxygen and 423412 (69.6%) did not. Throughout their stay in the hospital, 367835/689932 (53.3%) patients received some degree of oxygen supplementation; of these, 47191/453856 (10.4%) received NIV and 65617/684764 (9.6%) IMV.

Corticosteroids were administered to 169595/677012 (25.1%) patients. This includes 29942/64403 (46.5%) of those who received IMV, 141810/346679 (40.9%) of those who had oxygen therapy but not IMV, and 24526/314299 (7.8%) of those who had no oxygen therapy. On 16 June 2021, results for dexamethasone were released from the RECOVERY randomized controlled trial [20,21]. This trial found that dexamethasone reduced deaths for patients receiving IMV and oxygen therapy, but not among patients not receiving respiratory support. Of patients admitted since 16 June 2020, corticosteroids were given to 22922/48951 (46.8%) of those who received IMV, and 21521/274026 (7.9%) of those with no oxygen therapy.

Figure 15: Treatments in the entire population

(a) Proportions of patients receiving each treatment. Bars are annotated with a fraction indicating the number of individuals receiving each treatment over the number for which this information was non-missing. Oxygen therapy variable includes high flow nasal cannula, non-invasive ventilation, and invasive ventilation.

Table 5: Treatment use. The counts presented for treatments include all cases, not only cases with complete details of treatments (as expressed in the summary). Oxygen therapy variable includes high flow nasal cannula, non-invasive ventilation, and invasive ventilation.

Treatments	Present	Absent	Unknown
Oxygen therapy	367835 (0.53)	322097 (0.46)	9082 (0.01)

(b) Distribution of combinations of antimicrobial treatments and steroids administered during hospital stay, across all patients with completed hospital stay and recorded treatment data. Oxygen therapy variable includes high flow nasal cannula, non-invasive ventilation, and invasive ventilation.

Intensive Care and High Dependency Unit Treatments

Of the 699014 patients with data on ward admissions available, a total of 109599 (15.7%) were admitted at some point of their illness into an intensive care unit (ICU) or high dependency unit (HDU), among which, 33429 (53.9%) on the day of admission (47573patients without admission date data).

The range of treatments received whilst in ICU/HDU is presented in Figure 15 a and b. Of the patients admitted into ICU/HDU, 45957/50560 (90.9%) received antibiotics and 19260/49848 (38.6%) antivirals. 51760/59650 (86.8%) received some degree of oxygen supplementation, of which, 27761/58987 (47.1%) received NIV and 35749/58349 (61.3%) IMV.

A total of 47191 patients received non-invasive mechanical ventilation (NIV). The mean and median number of days from admission to receiving NIV were 2.2 days and 1 days respectively (SD: 3.6 days) – estimated from records on cases with complete records on dates of hospital admission and NIV onset (N = 31263). The mean and median durations for NIV were 3.7 days and 2 days respectively (SD: 3.3 days) – estimated based on only those cases which have complete NIV duration records (N = 7672).

A total of 65617 patients received invasive mechanical ventilation (IMV). The mean and median durations from admission to receiving IMV were 3.4 days and 2 days respectively (SD: 4.7 days) – estimated from records on cases with complete records on dates of hospital admission and IMV onset (N = 23328). The mean, median and SD for the duration of IMV – estimated based on all 33372 cases with complete records on IMV stays – were 10.2 days, 7 days and 9.7 days respectively.

Figure 16: Treatments in the ICU/HDU population

(a) Proportions of patients receiving each treatment. Bars are annotated with a fraction indicating the number of individuals receiving each treatment over the number for which this information was non-missing. Oxygen therapy variable includes high flow nasal cannula, non-invasive ventilation, and invasive ventilation.

(b) Distribution of combinations of treatments administered during ICU/HDU stay. Filled and empty circles below the x-axis indicate treatments that were and were not administered respectively. Oxygen therapy variable includes high flow nasal cannula, non-invasive ventilation, and invasive ventilation.

Key time variables

The key time variables are presented in Table 6. Patients tend to come to the hospital relatively early into their illness with a mean of 3 days and a median of 1 days from symptoms onset. 53.9% of ICU/HDU admissions occur within the first day at the hospital. The mean and median duration of hospital stay are 9.2 and 6 days, respectively. The duration of stay in ICU/HDU had a mean of 9.3 days and a median of 6 (SD: 9.2 days) – estimated on only those cases with complete records for ICU/HDU duration or ICU/HDU start/end dates (N = 57605).

Table 6: Key time variables. SD: Standard deviation; IQR: Interquartile range. Outliers (values greater than 120) were excluded prior to the computation of estimates.

Time (in days)	Mean	SD	Median	IQR
Length of hospital stay	9.2	9.2	7	3-12
Symptom onset to admission	3.0	4.1	1	0-5
Admission to ICU entry	1.7	3.1	0	0-2
Duration of ICU	9.3	9.2	6	3-13
Admission to IMV	3.4	4.7	2	0-5
Duration of IMV	10.2	9.7	7	3-15
Admission to NIV	2.2	3.6	1	0-3
Duration of NIV	3.7	3.3	2	1-5

The distribution of the number of days from admission to ICU admission is shown in Figure 18.

Figure 17: Distribution of lengths of stay for patients who were admitted to ICU/HDU: total length of stay for this group and length of stay within intensive care. This only includes cases with reported completed stays. The coloured areas indicate the kernel probability density of the observed data and the box plots show the median and interquartile range of the variable of interest.

The observed mean duration for the number of days from hospital admission to outcome (death or discharge) was 9, with SD 8.9 days and a median of 6 days. These estimates are based on all cases which have complete records on length of hospital stay (N = 607975). The distributions of length of hospital stay are presented In Figure 19a according to sex and 19b by patient age group.

Figure 18: Distribution of time (in days) from hospital admission to ICU admission. The figure displays data on only those cases with a reported ICU start date.

Figure 19: Distribution of length of hospital stay. This only includes cases with reported outcomes. The coloured areas indicate the kernel probability density of the observed data and the box plots show the median and interquartile range of the variable of interest.

(a) Distribution of length of hospital stay, according to sex.

(b) Distribution of length of hospital stay, according to age.

Outcomes

Outcomes are recorded for 632518 patients (90.5%), consisting of 481050 recoveries and 151468 deaths. Outcome records are unavailable for 66272 patients.

The overall estimated case fatality ratio (CFR) is 23.9% (95% CI 23.8-24.1) and is 37.1% (95% CI 36.8-37.4) for patients admitted to ICU/HDU - calculated out of those with data on outcome.

Figure 20: The distribution of patient status by number of days after admission. Patients with 'unknown' status have left the site at the time of report but have unknown outcomes due to missing data.

Figure 21: Cumulative patient numbers and outcomes by epidemiological week of admission (or, for patients infected in hospital, of symptom onset).

Discussion and conclusions

COVID-19 has tested the effectiveness of ISARIC's operating model: a global, open-source, collaborative approach set up 10 years ago to prevent illness and deaths from infectious disease outbreaks.

In January 2020, ISARIC launched its COVID-19 Clinical Characterisation Protocol (CCP) [https://isaric.org/research/covid-19-clinical-research-resources/clinical-characterisation-protocol-ccp/] and Case Report Form (CRF) [https://isaric.org/research/covid-19-clinical-research-resources/covid-19-crf/] as well as a free data management platform for researchers to upload their clinical data, globally. The ISARIC COVID-19 CCP database was open and publicly accessible from late January 2020, when less than a thousand COVID-19 cases had been reported globally; by mid-February 2020, the first patient record was successfully uploaded the platform; by mid-March 2020, the platform had ten thousand records.

Now, 24 months into the pandemic, with more than 800,000 records, the ISARIC clinical data platform has grown to become the largest international individual patient dataset of COVID-19 hospitalised cases. ISARIC is a model of global peer-to-peer collaboration, with contributions by 1701 sites in 60 countries, with similar representations of patients from high-income and low- and middle-income countries.

This report describes the features of COVID-19 patients in the entire cohort, made from cases accrued over 24 months with different contributions from various countries. Everyone can trace the evolution over time of the database through 16 previous versions of this report [https://isaric.org/research/covid-19-clinical-research-resources/evidence-reports/]. In addition, specific questions regarding clinical presentations, risks factors for outcomes, and trends are addressed through ad-hoc analyses.

Partners can submit ad-hoc request to perform analyses, to access the 800,000 case-based dataset, by using our Statistical Analysis Plan form (SAP; https://isaric.org/research/isaric-partner-analysis-frequently-asked-questions/). Once a SAP has been submitted, our statistical team assesses the plan for quality of research and feasibility of data analysis. Then, our clinical team provides feedback on clinical relevance and overlap with other analyses. Once this process has been completed, the SAP is sent to all ISARIC collaborators for the opportunity to review. This initial peer review process ensures that research is of the utmost quality and it helps encourage a truly participatory approach.

All ISARIC contributors are invited to participate in analyses through review and input on the SAP and the resulting publication. The outputs of our joint work are disseminated as widely as possible to inform patient care and public health policy. ISARIC aims to include the names of all those who contribute data in the cited authorship of publications, subject to the submission of contact details and confirmation of acceptance of the final manuscript within the required timelines, per ICMJE policies and the ISARIC publication policy.

What have our partners achieved Using the ISARIC and ISARIC4C databases, our partners have produced a broad range of evidence. More than 50 reports and manuscripts have been published to date, and a further 25 are in progress or under peer-review. https://isaric.org/document-library/ , https://isaric4c.net/outputs/ and https://isaric.org/research/covid-19-clinical-research-resources/accessing-covid-19-clinical-data/approved-uses-of-platform-data/.

True international collaboration during a pandemic is key to putting data into action. ISARIC partners have achieved this objective, and the results are shown in this special issue with half a million patient records.

Acknowledgement

This report is made possible through the efforts and expertise of the staff collecting data at our partner institutions across the globe, and the ISARIC Team. For a list of partners and team members, please visit rg/research/covid-19-clinical-research-resources/covid-19-data-management-hosting/covid19-clinical-data-contributors-list/.

Hospital for Tropical Diseases, Ho Chi Minh City.

Acknowledgements and Funders

This work was made possible by the UK Foreign, Commonwealth and Development Office; Wellcome [215091/Z/18/Z] [205228/Z/16/Z] [220757/Z/20/Z]; Bill & Melinda Gates Foundation [OPP1209135]; UK Medical Research Council Clinical Research Training Fellowship MR/V001671/1; the philanthropic support of the donors to the University of Oxford's COVID-19 Research Response Fund (0009109); CIHR Coronavirus Rapid Research Funding Opportunity OV2170359 and the coordination in Canada by Sunnybrook Research Institute; endorsement of the Irish Critical Care- Clinical Trials Group, co-ordination in Ireland by the Irish Critical Care- Clinical Trials Network at University College Dublin and funding by the Health Research Board of Ireland [CTN-2014-12]; the Rapid European COVID-19 Emergency Response research (RECOVER) [H2020 project 101003589] and European Clinical Research Alliance on Infectious Diseases (ECRAID) [965313]; the COVID clinical management team, AIIMS, Rishikesh, India; the COVID-19 Clinical Management team, Manipal Hospital Whitefield, Bengaluru, India; Cambridge NIHR Biomedical Research Centre; the dedication and hard work of the Groote Schuur Hospital Covid ICU Team; support by the Groote Schuur nursing and University of Cape Town registrar bodies coordinated by the Division of Critical Care at the University of Cape Town; the Liverpool School of Tropical Medicine and the University of Oxford; the dedication and hard work of the Norwegian SARS-CoV-2 study team; the Research Council of Norway grant no 312780, and a philanthropic donation from Vivaldi Invest A/S owned by Jon Stephenson von Tetzchner; Imperial NIHR Biomedical Research Centre; the Comprehensive Local Research Networks (CLRNs) of which PJMO is an NIHR Senior Investigator (NIHR201385); Innovative Medicines Initiative Joint Undertaking under Grant Agreement No. 115523 COMBACTE, resources of which are composed of financial contribution from the European Union's Seventh Framework Programme (FP7/2007- 2013) and EFPIA companies, in-kind contribution; the French COVID cohort (NCT04262921) is sponsored by INSERM and is funded by the REACTing (REsearch & ACtion emergING infectious diseases) consortium and by a grant of the French Ministry of Health (PHRC n°20-0424); Stiftungsfonds zur Förderung der Bekämpfung der Tuberkulose und anderer Lungenkrankheiten of the City of Vienna, Project Number: APCOV22BGM; Italian Ministry of Health "Fondi Ricerca corrente–L1P6" to IRCCS Ospedale Sacro Cuore–Don Calabria; Australian Department of Health grant (3273191); Gender Equity Strategic Fund at University of Queensland, Artificial Intelligence for Pandemics (A14PAN) at University of Queensland, the Australian Research Council Centre of Excellence for Engineered Quantum Systems (EQUS, CE170100009), the Prince Charles Hospital Foundation, Australia; grants from Instituto de Salud Carlos III, Ministerio de Ciencia, Spain; Brazil, National Council for Scientific and Technological Development Scholarship number 303953/2018-7; the Firland Foundation, Shoreline, Washington, USA; a grant from foundation Bevordering Onderzoek Franciscus; the South Eastern Norway Health Authority and the Research Council of Norway; Institute for Clinical Research (ICR), National Institutes of Health (NIH) supported by the Ministry of Health Malaysia; and preparedness work conducted by the Short Period Incidence Study of Severe Acute Respiratory Infection.

This work uses data provided by patients and collected by the NHS as part of their care and support #DataSavesLives. The data used for this research were obtained from ISARIC4C. We are extremely grateful to the 2648 frontline NHS clinical and research staff and volunteer medical students who collected these data in challenging circumstances; and the generosity of the patients and their families for their individual contributions in these difficult times. The COVID-19 Clinical Information Network (CO-CIN) data was collated by ISARIC4C Investigators. Data and Material provision was supported by grants from: the National Institute for Health Research (NIHR; award CO-CIN-01), the Medical Research Council (MRC; grant MC_PC_19059), and by the NIHR Health Protection Research Unit (HPRU) in Emerging and Zoonotic Infections at University of Liverpool in partnership with Public Health England (PHE), (award 200907), NIHR HPRU in Respiratory Infections at Imperial College London with PHE (award 200927), Liverpool Experimental Cancer Medicine Centre (grant C18616/A25153), NIHR Biomedical Research Centre at Imperial College London (award IS-BRC-1215-20013), and NIHR Clinical Research Network providing infrastructure support. We also acknowledge the support of Jeremy J Farrar and Nahoko Shindo
