49 **ABSTRACT**

50 **Background:** In response to supply shortages during the COVID-19 pandemic, N95 filtering facepiece  
51 respirators (FFRs or “masks”), which are typically single-use devices in healthcare settings, are routinely being  
52 used for prolonged periods and in some cases decontaminated under “reuse” and “extended use” policies.

53 However, the reusability of N95 masks is often limited by degradation or breakage of elastic head bands and  
54 issues with mask fit after repeated use. The purpose of this study was to develop a frame for N95 masks, using  
55 readily available materials and 3D printing, which could replace defective or broken bands and improve fit.

56 **Results:** An iterative design process yielded a mask frame consisting of two 3D-printed side pieces, malleable  
57 wire links that users press against their face, and cut lengths of elastic material that go around the head to hold the  
58 frame and mask in place. Volunteers (n= 41; average BMI= 25.5), of whom 31 were women, underwent  
59 qualitative fit with and without mask frames and one or more of four different brands of FFRs conforming to US  
60 N95 or Chinese KN95 standards. Masks passed qualitative fit testing in the absence of a frame at rates varying  
61 from 48 – 92% (depending on mask model and tester). For individuals for whom a mask passed testing, 75-100%  
62 (average = 86%) also passed testing with a frame holding the mask in place. Among users for whom a mask failed  
63 in initial fit testing, 41% passed using a frame. Success varied with mask model and across individuals.

64 **Conclusions:** The use of mask frames can prolong the lifespan of N95 and KN95 masks by serving as a substitute  
65 for broken or defective bands without adversely affecting fit. Frames also have the potential to improve fit for  
66 some individuals who cannot fit existing masks. Frames therefore represent a simple and inexpensive way of  
67 extending the life and utility of PPE in short supply. For clinicians and institutions interested in mask frames,  
68 designs and specifications are provided without restriction for use or modification. To ensure adequate  
69 performance in clinical settings, qualitative fit testing with user-specific masks and frames is required.

## 72 **BACKGROUND**

73 Frontline health care workers are vulnerable to infection by the severe acute respiratory syndrome  
74 coronavirus 2 (SARS-CoV-2), which causes coronavirus disease 2019 (COVID-19)(1): among healthcare workers  
75 at the height of the pandemic in Wuhan, China, approximately 29% are thought to have acquired COVID-19  
76 through hospital associated transmission (2). The most common routes of transmission for SARS-CoV-2 include:  
77 droplet transmission via direct face-to-face contact between patients and healthcare providers through coughing,  
78 sneezing, or speaking that aerosolizes virus, and aerosol-generating procedures such as intubation; indirect  
79 transmission by touching surfaces contaminated with virus followed by touching the face, nose or eyes is another  
80 suspected transmission route (3,4). Respiratory protection is an essential component of preventing hospital-based  
81 infections during the current COVID-19 pandemic, but an unprecedented demand for N95 filtering face mask  
82 respirators (FFRs; N95 masks) has led to severe shortages and many institutions have been forced to look for  
83 ways to prolong mask usability and even alternative solutions to respiratory protection.

84 The US Centers for Disease Control (CDC) recommends that healthcare workers dispose of N95 masks  
85 after each patient encounter. However, during the 2009 influenza A (H1N1) pandemic, which involved many  
86 fewer cases and deaths than the current COVID-19 pandemic, N95 respirator supplies were depleted (5,6). An  
87 evaluation of respiratory programs in California hospitals revealed that half of hospital managers interviewed  
88 (n=48) reported shortages of N95 respirators due to increased demand and slow delivery from suppliers (7). In  
89 response, guidelines were developed to preserve N95 supplies during shortages; these included “extended use”  
90 and “reuse.” “Extended use” is defined as the practice of wearing the same respirator for contact with several  
91 different patients infected with the same respiratory pathogen, without disposing of the respirator between  
92 patients. “Reuse” refers to the practice of using the same N95 respirator after removing it (“doffing”), for instance  
93 after a healthcare worker’s shift has ended, and then putting it back on (“donning”) prior to the next patient  
94 encounter. In the current COVID-19 pandemic, in which the shortage of PPE is more severe and widespread than  
95 in 2009, there is no specific regulation on the number donning/doffing cycles for N95 masks (8), although  
96 previous work found that masks consistently failed a test for fit quality after five consecutive donnings (9).

97 Individual healthcare settings have therefore enacted their own policies, often with insufficient information, to  
98 restrict respirator reuse and extended use (10) .

99 In the US, N95 FFRs are regulated by the National Institute for Occupational Safety and Health (NIOSH;  
100 part of the CDC) and the Food and Drug Administration (FDA) and must conform to standards set out in US 42  
101 CFR part 84. Other countries have analogous regulations, including the GB2626-2006 standard for KN95 masks  
102 in China and the EN 149:2001 standard for FFP2 masks in Europe. All such masks must exhibit three essential  
103 properties: (i) efficient filtration of small particles (ii) unencumbered inhalation and exhalation with a mask in  
104 place and (iii) snug fit to the face of a user so that all inhaled air passes through the filtering fabric. Mask reuse is  
105 often limited by problems achieving good fit as a result of breakage or degradation of elastic bands that hold the  
106 mask in place. In addition, increasingly poor respirator fit with reuse of N95 masks occurs due to degradation in  
107 nose clips and other components required to seal a mask tightly to a user's face (11).

108 The aim of this study was to develop a device to replace defective bands on N95 respirators without  
109 interfering with successful fit, thereby prolonging the lifespan of N95 respirators for both extended use and reuse.  
110 We also aimed to improve fit for individuals who failed baseline testing, thereby increasing the number of  
111 individuals who could benefit from low-cost respiratory protection. In the latter case, a specific aim was to  
112 improve the fit of KN95 masks, which are similar in performance to N95 FFRs (12) but are often observed to fail  
113 fit testing (13). We sought to use readily available materials and common 3D printing technology in a design that  
114 was made freely available for use or further modification.

115

## 116 **RESULTS**

### 117 **Frame design and fabrication**

118 Development of a modular mask frame model was inspired by the work of Dr. Christopher Wiles at the  
119 University of Connecticut, who has used 3D printed frames to enable use of alternative filter fabrics such as  
120 Halyard H600 sterilization wrap (14). We attempted to use the same relatively rigid 3D printed design to hold in  
121 place a standard 3M Model 8210 (St. Paul, MN USA) N95 industrial respirator. However, we found that the  
122 frame did not fit many individuals, particularly females with narrow faces. Previous research has shown that there

123 are key facial dimensions affecting respirator fit (15). We therefore sought to develop a frame with flexible  
124 components that could be molded by a user to assist in optimizing fit along these dimensions. This was achieved  
125 by using two malleable wire components (made of copper, steel or aluminum) to link two rigid lateral PLA  
126 frames fabricated by 3D printing (**Figure 1**). The final design was the result of an iterative process, which  
127 consisted of multiple rounds of mask and prototype fit testing on volunteers (students and healthcare  
128 professionals) with design modifications made based on user feedback. Direct interaction between users and  
129 designers facilitated the process. Key features added in the iterative design process included the production of two  
130 frame sizes to improve fit to faces of difference sizes and shapes, the addition of clips to help secure the mask  
131 frame to the underlying respirator and decrease the likelihood of the frame falling off during use, and  
132 modifications to the location and length of the frame head bands to make donning and doffing easier. We freely  
133 provide all designs in standard electronic formats for use by others or for further modification.

134         A total of six weeks was required to design, prototype, and fabricate mask frames for testing.  
135 The resulting design was flexible enough to conform to a diversity of face types and sizes and also rigid enough to  
136 seal masks to users' faces. Frames were fabricated from polylactic acid (PLA) on a standard 3D printer in less  
137 than 30 min at a cost of approximately 0.50 USD. Two sizes of lateral frames were printed in PLA and made  
138 available to participants: a "small" size (6.35 cm long) and a "regular" size (7.62 cm long) (**Figure 1A**).  
139 Additional features included radiused edges on the lateral frame (**Figure 1B**) to prevent the N95 FFR from being  
140 excessively deformed; deformation was observed with prototypes in which the edges were square or "V" shaped.  
141 We tested two different methods of attaching the malleable wire, one that used adhesive (**Figure 2A**) and one that  
142 involved twisting (**Figure 2B**). Note that slight modifications were necessary to accommodate 3D printed frames  
143 to the two wire attachment methods; however, the methods of wire attachment did not detectably affect comfort or  
144 function; design files for both prototypes are provided (**Additional Materials 1, 2, and 3**).

145         As a source of replacement elastic straps, we used non-latex phlebotomy tourniquets that are widely  
146 available and made of an FDA-approved material (Monprene<sup>(R)</sup> PR-23040). Elastic straps lock into slots on each  
147 side of the 3D-printed piece and are cut to a standardized length that fits around users' heads, just like factory-  
148 supplied straps (**Figure 3A, 3B**). Additional clips along the frame make it possible to secure any remaining

149 respirator bands to the frame. These clips are designed to optimize the pressure holding the mask firmly in place  
150 (**Figure 1C, 3C**). A frame with an attached mask is donned just like a mask without a frame: the respirator is  
151 brought to the face to cover the nose and mouth, the lower strap is brought up and over the top of the head and the  
152 upper strap is pulled up behind the head. The nosepiece of the mask frame is then press-fit, or otherwise bent to  
153 the shape of a user's nose (additional fitting instructions are provided in Methods; example fits shown in **Figure**  
154 **4**). Individual users were allowed to choose a frame size based on whether their faces were “small” or “regular.”

155

### 156 **Selection of FFRs for testing**

157 Four different types of N95-style FFRs were selected for testing: a 3M Model 1860 N95, 3M Model 8210  
158 N95, Kimberly Clark 46827/46767 (hereafter referred to as “duckbill”), and a Cooper KN95 (imprinted with  
159 number XK02-001-00010; Cooper USA; Los Angeles, CA). The 3M model 1860, available in both small and  
160 regular sizes, is a standard dome or cup-shaped respirator commonly used in healthcare settings (16) and is  
161 fabricated from media (fabric) that provides enhanced fluid and splash resistance (to ASTM Test Method F1862  
162 (17)). The Kimberly Clark regular (46767) and small (46827) models, like the 3M 1860 model, were used in  
163 healthcare settings prior to the pandemic and are fabricated according to ASTM standards and but are duckbill  
164 shaped instead of dome-shaped. We also tested an industrial 3M model 8210 mask, only available in a single  
165 standard size, that would not normally be used in a healthcare setting but whose temporary use is permitted in the  
166 US under an FDA Emergency Use Authorization (EUA) issued on April 3, 2020 (18). The Cooper flat-fold KN95  
167 respirator, available in one standard size, was selected as prototypical of a non-US manufactured FFRs whose use  
168 in healthcare is also allowed by an FDA EUA. Flat-fold respirators have a very different shape and fit from cup-  
169 style respirators. With KN95 masks it has also been observed that even when filtration efficiency meets  
170 specification fit can be problematic (19,20).

171

### 172 **Test subject demographics**

173 A total of 41 volunteers were involved in this study and consisted of attending physicians, resident  
174 physicians, medical students, nurses, medical assistants, clinic staff, and research scientists, with predominantly

175 female participants (ranging from 50% to 92% depending on the test group; **Table 1**). The proportion of female  
176 participants is representative of the healthcare workforce, which is predominantly female in the U.S. and  
177 worldwide (21). Of note, prior literature shows that women fail fit testing approximately 10% more frequently  
178 than men (22), suggesting a greater potential need for methods to improve fit with female FFR users. Individuals  
179 had a BMI ranging from 18.5 to 56.6 (averaging 25.5 for all groups). The study was approved by the Partners  
180 Healthcare Institutional Review Board (protocol 2020P001209) and all volunteers provided informed consent.

181

### 182 **Qualitative FFR fit testing**

183         Among the group of 41 volunteers, 32 were fit-tested with 3M model 1860 masks, 10 with 3M 8210, 25  
184 with Cooper KN95 masks, and 13 with the Kimberly Clark duckbills; not all masks could be tested on all  
185 individuals due to severely limited mask supply resulting from the COVID-19 pandemic. When available,  
186 information provided by the participants about which mask size they had previously used in a clinical setting was  
187 used to guide the selection of an appropriate respirator and mask frame size for this study (in all cases previous  
188 experience was with a small or regular 3M model 1860; **Table 1**). Qualitative fit testing was performed using a  
189 3M FT14 standardized hood and 3M FT-32 bitter testing solution; if a user could taste the aerosolized fluid, the  
190 test was judged to have failed. Fit was tested without a mask frame (the baseline condition) and with the 3D  
191 printed mask frame in place of the mask straps (the test condition; outlined in **Figure 5**). For 3M 8210 masks and  
192 Kimberly Clark duckbills, 9/10 (90%) and 12/13 (92.3%) of participants passed baseline testing without a 3D  
193 printed mask frame, respectively. For the 1860 and KN95 masks, baseline passing rates were lower at 28/32  
194 (87.5%) and 12/25 (48.0%), respectively. The passing rates for 1860, duckbill, and 8210 masks are consistent  
195 with previous literature demonstrating 82-95% fit rates across N95 respirator models (22,23). We then asked  
196 whether individuals for whom a mask passed qualitative fit testing in the baseline condition would also pass fit  
197 testing when elastic straps were removed (or allowed to hang down) and the masks held in place with a frame and  
198 replacement straps. For the 8210 (**Table 2; Figure 4B**), 100% of participants who passed qualitative fit testing at  
199 baseline preserved fit using a mask frame (9/9). For individuals who passed fit testing with an 1860 mask (**Table**  
200 **2; Figure 4A**), a KN95 mask (**Table 2; Figure 4D**), or a Kimberly Clark duckbill (**Table 2; Figure 4C**), the

201 passing rates with the 3D mask frame in the absence of the original mask straps were 22/28 (78.6%), 11/12  
202 (91.7%), and 9/12 (75.0%), respectively.

203 We also asked whether mask frames could improve fit for participants who failed baseline testing. For the  
204 Model 8210 mask, use of a frame made it possible for a single participant who did not fit a mask at baseline to  
205 pass. However, in no case was a frame able to improve fit of an 1860 mask (0/4 participants) or a Kimberly Clark  
206 duckbills (0/1 participants). In contrast, 46.2% (6/13 participants) for whom the KN95 mask did not pass fit  
207 testing under baseline conditions achieved an acceptable fit with a frame (**Table 2**).

208

## 209 **DISCUSSION**

210 In this paper we describe an iterative design process, involving multiple rounds of prototyping, clinical  
211 feedback, and design modification that resulted in a simple frame consisting of two identical 3D printed  
212 components (made in two sizes to accommodate different faces) and two pieces of malleable wire that together  
213 can hold an N95 or KN95 mask to users' faces in the absence of factory-supplied straps. Such mask frames are  
214 reusable and can be sterilized using 70% isopropyl alcohol wipes. Across a diverse group of volunteers, we found  
215 that mask frames were effective in replacing the original straps on all three masks tested. Results were mixed  
216 with respect to our additional goal of improving fit for participants who failed baseline qualitative fit-testing:  
217 frames were effective for some individuals and mask models and ineffective in other cases. The most promising  
218 results were obtained with KN95 flat-fold masks, for which achieving a good fit is known to be challenging(13).  
219 Replacing elastic straps broken or degraded with age, multiple donning/doffing cycles, or repeated  
220 decontamination and increasing the number of individuals who can fit KN95 masks would immediately impact  
221 PPE supplies for healthcare workers.

222 Multiple recent projects have attempted to develop reusable respirators to replace disposable N95s,  
223 especially within the global 3D printing community. For instance, the Copper3D NanoHack mask is printed with  
224 a PLA filament as a flat piece, and is manually assembled into a 3D configuration using hot air (e.g. hairdryer) or  
225 hot water (24); two reusable filter cartridges are then inserted into an intake port. The HEPA Mask (25), Creality  
226 Mask (26) and the Lowell Makes Mask (27) all involve similar 3D printed components in PLA but with different

227 variations in the filter holders. However, producing FFRs *de novo* involves several challenges, including securing  
228 a supply of suitable filters and achieving the proper fit for a wide range of users. This issue of fit has been tackled  
229 by printing masks in several sizes, experimenting with flexible materials or surface scanning an intended user's  
230 face and creating a custom-fit device (World Advanced Saving Project (WASP)(28) and Bellus3D (29)).  
231 However, throughput is currently limited (30) and in some cases supplies of the necessary filters have been  
232 largely depleted (31). Thus, conventional N95 masks are likely to remain an essential component of PPE during  
233 the current pandemic (32).

234           How great is the need for extending usable mask life? Historical guidance by the National Institute for  
235 Occupational Safety (NIOSH) specifies that the useful lifetime of NIOSH-approved FFRs is limited by filter load  
236 and that any filter or mask should be replaced if it becomes soiled, damaged, or causes noticeably increased  
237 breathing resistance (33). In environments that generate high cumulative filter loading, the recommended  
238 maximum lifespan for N95 respirators is eight hours and it is standard practice in healthcare to dispose of N95  
239 masks after each patient encounter. However, during the first SARS pandemic, the CDC stated that “health care  
240 facilities may consider reuse as long as the device has not been obviously soiled or damaged (e.g. creased or  
241 torn)” and “if a sufficient supply of respirators is not available (34).” Multiple FDA Emergency Use  
242 Authorizations (EUAs) issued during the COVID-19 pandemic have further expanded on this concept and led to  
243 the use of a wide variety of decontamination methods including UV germicidal irradiation, vaporous and ionized  
244 hydrogen peroxide (VHP/iHP) and moist heat (35–42), all of which promise to enable N95 reuse (for instance, the  
245 FDA EUA for the Battelle decontamination system permits up to 20 vaporous hydrogen peroxide  
246 decontamination cycles per respirator(43)) . However, mask reuse is frequently limited by breakage or  
247 degradation of the elastic bands that hold a mask in place and it has been reported that N95 masks stored in  
248 preparation for a pandemic also have a high rate of band failure (11).

249           Moreover, quantitative fit testing (e.g. using a PortaCount quantitative fit testing apparatus, TSI Inc.,  
250 Shoreview, MN) has shown that multiple donnings and doffings degrade fit independent of band failure. Bergman  
251 et al. (9) found that, after five consecutive donnings, fit factors consistently dropped below 100, the cut-off  
252 between passing and failing the test. Vuma et al. (44) showed that, when 25 tests subjects performed consecutive

253 N95 donning and doffing operations, fit factor differed significantly between the first and the sixth re-donnings.  
254 After the sixth donning, only ~68% of study subjects achieved a passing fit. Degsys et al. (45) found that an  
255 increase in fit failures was associated with an increasing number of shifts, each of which was associated with a  
256 donning and doffing cycle (median 4 shifts) and increasing hours of use (median 14 hours). It is thought that  
257 failures of fit with prolonged use of N95 masks involves degradation of the malleable nose clips and other  
258 components that help seal a mask tightly to a user's face. Additionally, mask fit is adversely affected by repeated  
259 cycles of decontamination across a variety of methods (including heat and ethanol) (46). If undetected, poor fit  
260 causes air to flow around the mask (11) potentially increasing disease transmission.

261 Problems with fit are not restricted to masks that are being reused: it has previously been reported that  
262 even with new masks, about 17% of users will fail fit testing with any specific model of N95 or N95-equivalent  
263 mask (23). The fit failure rate for KN95s has not been extensively quantified in the literature, but available studies  
264 suggest that fit failure is an issue with a majority of KN95 models (40). Improving fit by using a frame would  
265 therefore be helpful even in non-pandemic situations. The problem with failure to fit any mask is made worse in a  
266 pandemic by shortages in alternative forms of respiratory protection (e.g., powered air-purifying respirators(47)).  
267 Thus, both pandemic and non-pandemic respiratory protection presents a substantial need for devices – such as  
268 the mask frames described here - to extend the useful lifetime of FFRs, such as N95 or KN95 masks, or improve  
269 fit of new masks. It must be noted, however, that clinical data supporting extended use and reuse of N95 masks,  
270 with or without decontamination, remains limited. Concerns about extended use and reuse involve not only fit and  
271 the adequacy of the seal to a user's face (45), but also potential infection risks acquired during donning/doffing  
272 (since the outer surface of respirators can be contaminated with infectious agents that can be transferred to a user  
273 (48)) and reductions in filtration efficiency over time. The mask frames described here address only the first of  
274 these issues.

275

## 276 **Limitations of this study**

277 This study has several limitations; most notably, that sample sizes and the number of mask models tested  
278 were small. We were unable to follow up preliminary but promising data that frames can improve the fit of KN95

279 masks. These limitations reflect continuing shortage in FFRs of all types and our inability to divert more than a  
280 small number of masks from hospital or staff use to a research project. In particular, results would be improved by  
281 finding a much larger number of participants who failed baseline fit testing and from whom multiple models of  
282 masks could be evaluated with and without frames. For all of the masks used in this study straps were artificially  
283 broken or allowed to hang free; to better represent the real-world use case it will be necessary to perform fit  
284 testing with and without a mask frame after extended N95 mask use in a clinical setting. Our data suggest that the  
285 precise shape of a mask and the properties of the material may determine whether a frame can successfully  
286 substitute for original straps or improve fit. Additional research will be required to identify these variables and  
287 address them. Ideally, all of these issues will become increasingly possible to address as supply disruptions recede  
288 and sufficient FFRs can be dedicated to research studies.

289

## 290 **CONCLUSIONS**

291 The use of the 3D-printed mask frames described in this study can prolong the lifespan of N95 and KN95  
292 masks by serving as a substitute for broken or defective bands without adversely affecting fit. Frames also have  
293 the potential to improve fit for some individuals who cannot use existing masks. Both defective straps and poor fit  
294 are limiting factors in extended mask use and in the reuse of masks after decontamination, as masks with either  
295 defect are currently discarded. Thus, improving mask fit through use of a frame is expected to help offset urgent  
296 respirator supply shortages during the COVID-19 pandemic and also help after the pandemic passes. All design  
297 files and testing results are included in this manuscript and available for reuse without restriction; design  
298 information is also available via the PanFab website (<https://www.panfab.org/>). Our prototyping and testing  
299 efforts took place over the span of approximately 6 weeks and use of our designs should save substantial time  
300 relative to designing mask frames *de novo*. However we suggest that each group perform its own fit testing with a  
301 representative group of users. We believe that the results and designs presented here are one step in improving the  
302 supply and effectiveness of PPE in this pandemic and in increasing our collective ability to respond to future  
303 healthcare crises.

304

## 305 **METHODS**

### 306 **Mask Frame Software and Design**

307 3D printed mask frames were designed in Rhinoceros<sup>(R)</sup> Rhino 6 (**Figure 1**) in two sizes. A 3D model (.3dm) of  
308 the lateral frames were exported in Rhino 6 to a Standard Tessellation Language (.STL) file. The .STL was  
309 uploaded to 3dPrinterOS, a cloud based 3D printing service. 3dPrinterOS converted the .STL to a G-code file,  
310 which contains machine commands that control the 3D printers' movement and deposition of material, and sent to  
311 a 3D printer. Print settings were chosen by using the default values for the 3dPrinterOS customized for the  
312 Dremel 3d45 3D printer, including print nozzle temperature of 230°C and print bed temperature of 60°C. Other  
313 printer settings included a standard layer height of .3mm, a 1.2mm sidewall shell thickness, 10% infill in a 'grid'  
314 pattern, and a top and bottom layer shell thickness of 2mm.

315

### 316 **3D Printer Model and Hardware**

317 Dremel branded 1.75 mm diameter PLA was used on a Dremel 3d45 3D printer for printing all components. The  
318 printer has a .4mm nozzle extrusion width, and a build volume of 10 x 6.7 x 6 inches (254 x 152 x 170 mm). Print  
319 time for one regular sized mask frame was ~ 30 min.

320

### 321 **Mask Frame Assembly**

322 Two methods of mask frame assembly were used, each of which involved a slight modification to the 3D printed  
323 lateral frame. **Method 1 (Figure 2A)** used an adhesive, cyanoacrylate (also known as super glue), to join the  
324 mask frame components; the prototype design is shown in **Figure 1**. Method 1 assembly sequence is as follows:  
325 gather components (2 flexible wires cut to 127 mm, 2 PLA lateral frames, and 1 bottle of superglue). (1) Place  
326 one drop of super glue in the lateral frame joint. (2) Insert wire into joint. Follow instructions accompanying super  
327 glue for holding wire in place to properly allow the glue to set and cure. (3) Repeat for each joint.

328 **Method 2 (Figure 2B)** involved a mechanical connection in which formable wire was twisted to join mask frame  
329 components. Method 2 assembly sequence is as follows: gather components (2 flexible wires cut to 195 mm and  
330 two PLA lateral frames that have a hole through the joint). (1) Push wire through the joint in the lateral frame. (2)

331 Loop wire back. (3) Twist wire around itself. Pliers are recommended to assist in bending and twisting of wire to  
332 ensure secure twist. (4) Repeat for each connection.

333

### 334 **Band and Clip Attachment**

335 Based on prior work creating 3D printed mask frames by colleagues at the University of Connecticut (14), the  
336 band material used for this study was Monprene<sup>(R)</sup> PR-23040 in the following size: 0.25 in x 0.015 in (Teknor  
337 Apex; Pawtucket, RI). Two strips of elastic 305 and 330 mm in length were cut for the 1860 and KN95 masks,  
338 and two strips 356 and 381 mm in length were cut for the 8210. A knot was tied at each end of each band,  
339 approximately 25 mm from the end of the band. The knot locks into each slot in the PLA frame as shown in  
340 **Figure 3A** and **Figure 3B**. The clips along the PLA frame secure to existing bands of the respirator, if still  
341 present, to secure the frame to the mask (**Figure 3C**).

342

### 343 **Donning, Doffing and Sterilization**

344 Once the mask frame is attached to the respirator using the clips, the respirator is donned just like a respirator  
345 without the frame. Holding the respirator and mask frame in the palms of the hands, the respirator is brought to  
346 the face to cover the nose and mouth, and the mask frame should not pass outside the borders of the mask. The  
347 bottom strap attached to the mask frame is brought up and over the top of the head and placed at the nape of the  
348 neck below the ears. The upper strap is pulled up behind the head and placed at the crown of the head. Then, the  
349 nosepiece of the mask frame is manipulated in the shape of the user's nose until a secure seal and good fit are  
350 achieved (**Figure 4**). A seal check is performed by placing both hands over the mask and exhaling. If air leakage  
351 is observed, there is not a proper seal. Re-adjusting the nosepiece or pulling the straps tighter should be attempted  
352 until a proper seal is obtained. Mask frames can be sterilized using 70% isopropyl alcohol wipes.

353

### 354 **Qualitative Fit Testing**

355 This study was approved by the Partners Healthcare Institutional Review Board (protocol #2020P001209). All  
356 subjects underwent qualitative fit testing at the Dana-Farber Cancer Institute during May-June, 2020. Participants

357 included attending physicians, medical students and researchers. Qualitative fit testing using a 3M FT14 hood and  
358 3M FT-32 bitter testing solution was performed over two different testing sessions, both consisting of tests  
359 without the mask frame (baseline) and with the 3D printed mask frame (**Figure 5**). Qualitative fit failure occurred  
360 if the participant could taste the solution (bitter taste). Four different models of respirators were tested: 1860,  
361 8210, duckbill, and KN95. Data was analyzed using Prism version 8 (GraphPad).

369

### 370 **DECLARATIONS**

#### 371 **Ethics approval and consent to participate**

372 The Partners Healthcare Institutional Review Board approved this study (protocol #2020P001209).

373

#### 374 **Consent for publication**

375 Consent for publication has been obtained from the study participants. Written informed consent for publication  
376 was obtained from the study participants pictured in **Figure 4**. A copy of the consent form is available for review  
377 by the Editor of this journal.

378

#### 379 **Availability of data and materials**

380 All data generated or analyzed during this study are included in this published article and its supplementary  
381 information files.

382

383 **Competing interests**

- 384 • A Mostaghimi is a consultant or has received honoraria from Pfizer, 3Derm, and hims and has equity in Lucid  
385 Dermatology and hims. He is an associate editor for JAMA Dermatology. Mostaghimi declares that none of  
386 these relationships are directly or indirectly related to the content of this manuscript.

550 **FIGURES**

551

552 **Figure 1.** Mask frame components. **A)** PLA lateral frames in two sizes: the small size is 6.35 cm long and regular  
553 size is 7.62 cm long. **B and C)** Assembled mask frames consisting of both mask frame and malleable wire  
554 (copper, steel, or aluminum). Note that this mask frame involves attaching 3D printed components to wire using  
555 cyanoacrylate “superglue”. A mechanical attachment method is described in Figure 2.

556

557 **Figure 2.** Methods for mask frame assembly. **A)** Method One for assembly of mask frame for N95 respirators  
558 utilizing glue adhesive. 1) One drop of cyanoacrylate superglue is placed into the end slot for the wire within the  
559 PLA lateral frame. 2) The end of a wire is inserted into the slot. 3) All four wire ends are inserted into the PLA  
560 slots as shown to complete the frame. **B)** Method Two for assembly of mask frame for N95 respirators using wire  
561 alone (no adhesive). 1) Wire is pushed through the opening in the PLA lateral frame. 2) The wire is looped back  
562 and 3) twisted around itself using pliers. 4) This process is repeated for each of the 4 total connections.

563

564

565 **Figure 3.** Attachment of the head band to a mask frame. **A)** A knot is tied at the end of each band and the band is  
566 then slid into and locked in place using the PLA slot **B)** Mask frame with bands **C)** Clip attachment of the frame  
567 to the bands on the 3M N95 Model 1860 respirator.

568

569

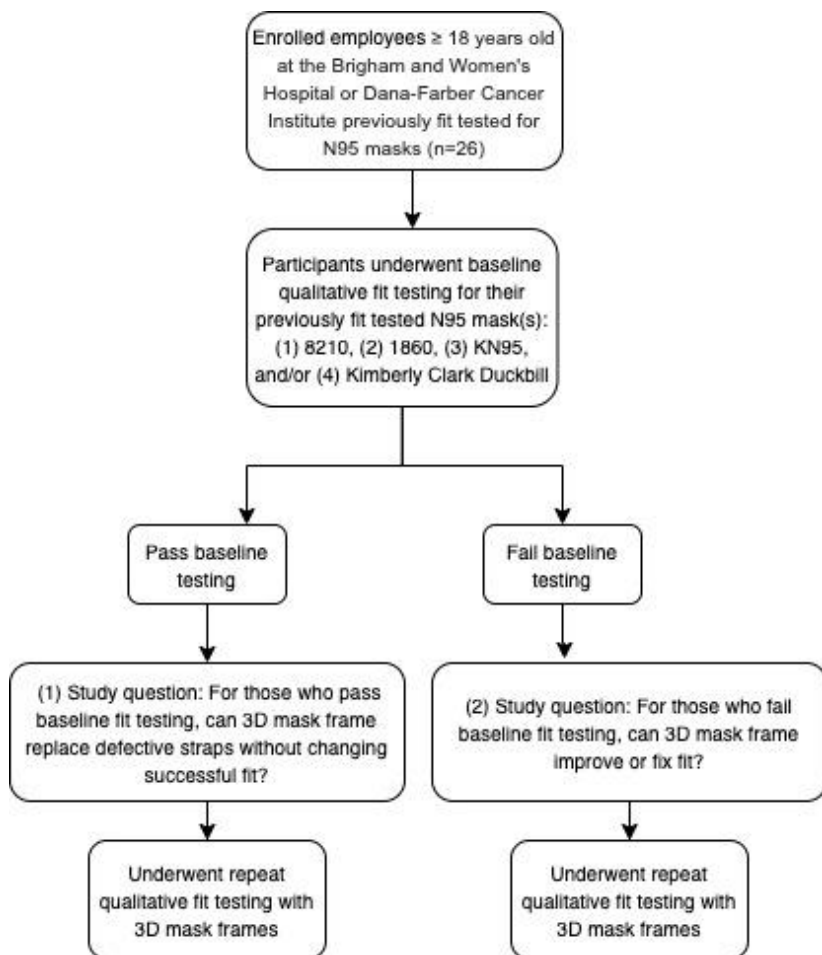

570

571 **Figure 4.** Properly donned mask frames and respirators on three different volunteers. **A)** A 3M 1860 N95 domed  
572 healthcare respirator, **B)** a 3M 8210 N95 domed industrial respirator (note the a valve-less version of the model is  
573 used in healthcare settings but was not always available for testing due to widespread respirator shortages) **C)** a  
574 Kimberly Clark duckbill, and **D)** a KN95 flat-fold respirator. The bands should be sufficiently tight and the  
575 nosepiece manipulated to achieve a good seal.

586 **TABLES**

587 **Table 1.** Demographics and characteristics of participants undergoing baseline fit testing. SD = standard  
588 deviation.

	<b>No. (%) or Mean +/- SD (range)</b>			
<b>Characteristic</b>	<b>1860 N95 respirators (n=32)</b>	<b>8210 N95 respirators (n=10)</b>	<b>KN95 Respirators (n=25)</b>	<b>Kimberly Clark duckbill respirators (n=13)</b>
<b>Gender</b>				
Female	18 (56.3%)	5 (50%)	22 (88%)	12 (92.3%)
Male	14 (43.8%)	5 (50%)	3 (12%)	1 (8.3%)
<b>Age</b>	37.6 +/- 10.7	30.7 +/- 5.7	36.5 +/- 12.5	33.6 +/- 10.2
<b>Ethnicity</b>				
Asian/Pacific Islander	10 (31.3%)	4 (40%)	5 (20%)	0
White/Caucasian	10 (31.3%)	6 (60%)	8 (32%)	3 (25%)
Black/African American	10 (31.3%)	0 (0%)	9 (36%)	8 (66.7%)
Hispanic/Latino	2 (6.3%)	0	3 (12%)	2 (16.7%)
<b>Body mass index (BMI)</b>	25.7 +/- 7.8	23.4 +/-2.7	26.6 +/- 8.5	30.5 +/- 10.2
<b>Healthcare role</b>				
Attending physician	16 (50%)	1 (10%)	6 (24%)	1 (8.3%)
Resident physician	0	2 (20%)	2 (8%)	0
Medical student	2 (6.3%)	3 (30%)	2 (8%)	0
Graduate student	0	1 (10%)	0	0
Researcher	2 (6.5%)	3 (30%)	1 (4%)	0
Nurse	4 (12.5%)	0	5 (20%)	3 (25%)
Medical Assistant	5 (15.6%)	0	5 (20%)	5 (38.5%)

Clinic Staff	3 (9.4%)	0	4 (16%)	4 (30.8%)
<b>Mask size (previously fitted)</b>				
Small	10 (31.3%)	5 (50%)	6 (24%)	1 (8.3%)
Regular	22 (68.8%)	5 (50%)	19 (76%)	12 (92.3%)

589 **Table 2.** Qualitative fit testing results using mask frames.

**Number Passed Qualitative Fit Test**

<b>Mask Type</b>	Baseline Testing of Mask without Frame	Participants Who Passed Baseline: Mask with Frame (Preserving Fit)	Participants who Failed Baseline: Mask with Frame (Improving Inadequate Fit)
8210 model (Total n=10)	9/10 (90%)	9/9 (100%)	1/1 (100%)
1860 model (Total n=32)	28/32 (87.5%)	22/28 (78.6%)	0/4 (0%)
KN95 model (Total n=25)	12/25 (48.0%)	11/12 (91.7%)	6/13 (46.2%)
Kimberly Clark duckbill model (Total n=13)	12/13 (92.3%)	9/12 (75.0%)	0/1 (0%)
