48 **ABSTRACT**

49 *Background*

50 Current strategies for preventing severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2)
51 infections are limited to non-pharmacological interventions. Hydroxychloroquine (HCQ) has been
52 proposed as a postexposure therapy to prevent Coronavirus disease 2019 (Covid-19) but definitive
53 evidence is lacking.

54 *Methods*

55 We conducted an open-label, cluster-randomized trial including asymptomatic contacts exposed to a
56 PCR-positive Covid-19 case in Catalonia, Spain. Clusters were randomized to receive no specific therapy
57 (control arm) or HCQ 800mg once, followed by 400mg daily for 6 days (intervention arm). The primary
58 outcome was PCR-confirmed symptomatic Covid-19 within 14 days. The secondary outcome was SARS-
59 CoV-2 infection, either symptomatically compatible or a PCR-positive result regardless of symptoms.
60 Adverse events (AEs) were assessed up to 28 days.

61 *Results*

62 The analysis included 2,314 healthy contacts of 672 Covid-19 index cases identified between Mar 17 and
63 Apr 28, 2020. A total of 1,198 were randomly allocated to usual care and 1,116 to HCQ therapy. There
64 was no significant difference in the primary outcome of PCR-confirmed, symptomatic Covid-19 disease
65 (6.2% usual care vs. 5.7% HCQ; risk ratio 0.89 [95% confidence interval 0.54-1.46]), nor evidence of
66 beneficial effects on prevention of SARS-CoV-2 transmission (17.8% usual care vs. 18.7% HCQ). The
67 incidence of AEs was higher in the intervention arm than in the control arm (5.9% usual care vs 51.6%
68 HCQ), but no treatment-related serious AEs were reported.

69 *Conclusions*

70 Postexposure therapy with HCQ did not prevent SARS-CoV-2 disease and infection in healthy
71 individuals exposed to a PCR-positive case. Our findings do not support HCQ as postexposure
72 prophylaxis for Covid-19.

73

74 **ClinicalTrials.gov registration number:** NCT04304053

75

76 INTRODUCTION

77 Coronavirus 2019 disease (Covid-19) is a rapidly emerging infection caused by the severe acute
78 respiratory syndrome coronavirus 2 (SARS-CoV-2). The rate of new cases among contacts (secondary
79 attack rate) has been estimated as 10 to 15%.¹⁻⁴ The current infection control strategy is based on social
80 distancing and isolation of cases and contacts.⁵ The effectiveness of the latter depends on the promptness
81 of the intervention, level of contact tracing, and level of isolation compliance.⁶ Unfortunately, real-world
82 constraints for implementing full effective measures have resulted in SARS-CoV-2 spread in many
83 countries.

84 Postexposure prophylaxis of healthy contacts is among the measures used for outbreak control of several
85 infectious diseases, for example, in pandemic influenza.⁷ No agent is known to be effective in preventing
86 SARS-CoV-2 infection or disease, but several drugs have shown antiviral activity in the laboratory,
87 including the aminoquinolines hydroxychloroquine (HCQ) and chloroquine.⁸ In-vitro results showed that
88 these drugs block the SARS-CoV-2 viral spread in cell cultures⁹⁻¹¹ and that HCQ was more effective at
89 impairing SARS-CoV-2 viral replication compared to chloroquine.¹¹ To date, only one RCT has reported
90 on HCQ for postexposure prophylaxis for Covid-19.¹² However, concerns have been raised about the trial
91 design, primarily because most participants were diagnosed with an influenza-like illness based on
92 symptoms alone, and only 20% of their Covid-19 outcome was confirmed with PCR.

93 We investigated the efficacy and safety of HCQ to prevent secondary PCR-confirmed symptomatic
94 Covid-19 (confirmed Covid-19) and SARS-CoV-2 infection in contacts exposed to a PCR-positive
95 Covid-19 case during the outbreak in Catalonia, the region with the second highest number of Covid-19
96 cases in Spain.

97

98 **METHODS**

99 *PARTICIPANTS*

100 We included adult individuals ≥ 18 years of age with a recent history of close contact exposure to a PCR-
101 confirmed Covid-19 case (i.e., > 15 minutes within two meters, up to seven days before enrolment) and
102 absence of Covid-19-like symptoms on the two weeks preceding enrolment, as either a healthcare worker,
103 a household contact, a nursing home worker or a nursing home resident. Contacts with Covid-19-like
104 signs and symptoms at the time of the baseline visit were considered unpreventable Covid-19 events and
105 were not enrolled in the study. All eligibility criteria are listed in the Supplementary Appendix.

106 *TRIAL DESIGN AND OVERSIGHT*

107 This was an open-label, phase 3 cluster-randomized trial conducted from Mar 17 to Apr 28, 2020, during
108 the Covid-19 outbreak, in three out of nine health administrative regions in Catalonia, Spain: *Catalunya*
109 *central*, *Àmbit Metropolità Nord*, and *Barcelona Ciutat* (total target population 4,206,440 people; Fig. S1,
110 Supplementary Appendix).

111 Study candidates were screened using the electronic registry of the Epidemiological Surveillance
112 Emergency Service of Catalonia (SUVEC) of the Department of Health. During the Covid-19 outbreak in
113 Catalonia, a public health ordinance required all patients who tested positive for Covid-19 in any of the
114 designated diagnostic laboratories to be notified to the SUVEC.¹³

115 The study protocol and subsequent amendments, available at NEJM.org, were approved by the
116 institutional review board of Hospital Germans Trias Pujol, and the Spanish Agency of Medicines and
117 Medical Devices. All participants provided written informed consent.

118 *TRIAL PROCEDURES*

119 Following a similar approach as the ring vaccination trial “Ebola Ça Suffit!”,¹⁴ we defined study clusters
120 (called rings) of healthy individuals (contacts) epidemiologically linked to a PCR-positive Covid-19 case

121 (index case). All contacts in a ring were simultaneously cluster-randomized (1:1) to either a control arm
122 or an intervention arm. Randomization was performed remotely by a member of the study team not
123 involved in participants' enrollment. Following ring randomization, we verified the selection criteria of
124 individual candidates and obtained informed consent for enrollment. The allocation was revealed to
125 participants after providing written consent on day 1 (baseline). Participants allocated in the control arm
126 received no treatment aside from usual care, whereas those in the intervention arm received HCQ
127 (Dolquine[®]) 800 mg on day 1, followed by 400 mg once daily for six days. The dose and regimen of HCQ
128 were chosen based on pharmacokinetic simulations to achieve plasma and lung concentrations above the
129 SARS-CoV-2 half-maximal effective concentration observed in-vitro¹¹ for 14 days (details provided in
130 the Study Protocol).

131 By the time of trial conduct, quarantine was mandatory for all exposed contacts, according to the National
132 Department of Health guidelines; hence the likelihood that a participant could be exposed to other cases
133 was low. Covid-19 index cases that generated the rings were enrolled in a nested trial aimed at
134 investigating the efficacy of early treatment with hydroxychloroquine as therapeutic intervention for
135 Covid-19 outpatients. Laboratory technicians were unaware of participants' treatment, treatment
136 response, and previous PCR results during the entire follow-up period.

137 All contacts were visited at home or workplace on day 1 for medical exam, and baseline nasopharyngeal
138 swab collection for SARS-CoV-2 RT-PCR test and viral load. Symptoms surveillance consisted of active
139 monitoring by phone on days 3 and 7, and passive monitoring whenever the participant developed
140 symptoms (i.e., participants were advised to call the research team). Participants who developed
141 symptoms were visited the same day (unscheduled visit) by the outbreak field team for nasopharyngeal
142 swab collection. All participants were visited at home on day 14 for nasopharyngeal swab collection, and
143 finger-prick for IgM/IgG rapid test. Safety, medication adherence (i.e., treatment and number of doses
144 taken), and crossover (i.e., unplanned conversion of control to intervention) were assessed using self-
145 reports collected in telephone interviews on days 3, 7, and 28. Details on procedures performed at each

146 visit and laboratory methods for SARS-CoV-2 identification and quantification (Fig. S2) are provided in
147 the Supplementary Appendix.

148 *OUTCOMES*

149 The primary outcome was the onset of a confirmed Covid-19 episode, defined as symptomatic illness (at
150 least one of the following symptoms: fever, cough, difficulty breathing, myalgia, headache, sore throat,
151 new olfactory and taste disorder(s), or diarrhea) and a positive SARS-CoV-2 RT-PCR test. The primary
152 outcome was assessed in all asymptomatic individuals, irrespective of the PCR result; in a post hoc
153 analysis, we explored the outcome in individuals with positive and negative PCR separately. Time-to-
154 event was defined as the number of days from the date of randomization/exposure to the confirmed date
155 of the onset of symptomatic illness.

156 The secondary outcome was the incidence of SARS-CoV-2 infection, defined as either the RT-PCR
157 detection of SARS-CoV-2 in a nasopharyngeal specimen or the presence of any of the aforementioned
158 symptoms compatible with Covid-19. The rationale for this outcome was to encompass definitions of
159 Covid-19 used elsewhere^{12,15} and all possible viral dynamics. We, therefore, assumed that if clinical
160 suspicion is high, infection should not be ruled out based on a negative PCR alone—particularly early in
161 the course of infection.¹⁵ Participants who were hospitalized or died and whose hospital/vital records
162 listed Covid-19 as the main diagnosis (including PCR confirmation) were also considered for the primary
163 and secondary outcomes. We also measured serological positivity (IgM/IgG) of contacts at day 14. Safety
164 outcomes included the frequency and severity of adverse events (AE), serious AE (SAE), and AE of
165 special interest (e.g., cardiac) up to 28 days from treatment start. Causality was assessed by an external
166 panel of pharmacovigilance consultants.

167 *STATISTICAL ANALYSIS*

168 With an enrollment target of 95 clusters per trial group¹⁶ —15 participants per cluster and intraclass
169 correlation of 1.0— the initial design yielded 90% power to detect a difference of 10% in the incidence,

170 with expected incidence of 15% in the control arm. Owing to the limited information available by March
171 2020 regarding the cluster size and the incidence of Covid-19 after exposure, the protocol prespecified a
172 sample-size re-estimation at the interim analysis. This re-estimation was aimed at maintaining the ability
173 (80% power) to detect a reduction from 6.5% to 3% of the primary outcome, yielding 320 clusters per
174 trial group with 3.5 participants per cluster.

175 The primary efficacy analysis was performed on the intention-to-treat (ITT) population, which included
176 all randomized subjects with complete outcome data. We decided not to impute outcome data to
177 participants with missing measurements because this approach would have biased the incidence of
178 secondary Covid-19 events. Sensitivity analyses were performed with the per-protocol (PP) population in
179 participants who completed the trial according to the protocol. The safety population included all
180 participants who received any trial intervention, including usual care.

181 The cumulative incidence in primary, secondary, and safety outcomes was compared at the individual
182 level using a binomial regression model with robust sandwich standard errors to account for clustering
183 within rings.¹⁷ We defined a generalized linear model with a binomial distribution and a logarithm link
184 function to estimate the relative risk (RR) as a measure of effect.¹⁸ The individual-level variables we
185 adjusted for are age, gender, region, and time of exposure. We did additional pre-specified analyses to
186 assess the consistency of treatment effects in subgroups defined according to the viral load of the contact
187 at baseline, viral load of the index case, place of exposure, time of exposure to the index case. Survival
188 curves by study groups on time-to-event outcomes were compared using a Cox proportional hazards
189 model with a cluster-level frailty term to adjust for clustering.¹⁹ The significance threshold was set at a
190 two-sided alpha value of 0.05, unless otherwise indicated, and all statistical analyses were conducted in R
191 version 3.6.2.²⁰

192 **RESULTS**

193 *CHARACTERISTICS OF STUDY PARTICIPANTS*

194 Between Mar 17 and Apr 28, 2020, we assessed 754 Covid-19 index cases for eligibility; 672 of them
195 were selected for defining the corresponding clusters, which included 4,399 contacts (Fig. 1). 1,874
196 (42.6%) of the 4,399 contacts were not enrolled because of at least one exclusion criteria, including
197 contacts presenting Covid-19-like symptoms before enrolment ($n = 537$). Additionally, 211 (8.4%) of
198 2,525 enrolled contacts were excluded from ITT analysis because of screening failure or missing PCR
199 results on day 14, yielding an ITT population of 2,314 contacts. During follow-up, 64 participants had a
200 protocol deviation regarding the intervention (PP population of 2,250 contacts).

201 The demographic, clinical, and epidemiological characteristics of participants at baseline were similar in
202 the two study arms (Table 1, PP analysis in the Supplementary Appendix). The mean age of contacts was
203 48.6 years (SD 19.0) and the PCR test at baseline was negative in 87.8% of them (2,000 of 2,314).
204 Overall, 55.6% of the participants (1,287 of 2,314) reported chronic health conditions. The median length
205 from exposure to enrolment was 4.0 (IQR 3.0–6.0) days. The size of clusters was similar in both arms
206 (median 2.0 vs. 2.0; $P = 0.25$). Exposure was predominantly from an index case with moderate-to-high
207 viral load shedding (460 of 549 [83.8%] index cases with available viral load assessment). Health care
208 workers and nursing home workers accounted for 60.3% (1,395) of the participants; 27.7% (640) were
209 enrolled as household contacts, and 12.7% (293) as nursing home residents. Overall, 67.2% (1,555) of
210 participants reported routine use of masks at the time of exposure, and 6.2% (144) of contacts continued
211 to sleep in the same room as the index case.

212 *PRIMARY OUTCOME*

213 During the 14-day follow-up, 138 (6.0%) of 2,314 participants experienced a PCR-confirmed,
214 symptomatic Covid-19 episode. The primary outcome was similar in the control arm (6.2%; 74/1,198)

215 and the intervention arm (5.7%; 64/1,116; RR 0.89 [95% CI 0.54–1.46]) (Table 2). The incidence of each
216 of the components of the primary outcome did not differ significantly between groups.

217 Overall, the incidence of confirmed Covid-19 was higher in participants who tested positive in the
218 baseline PCR (Table 2); 3.4% (74 of 2,000) participants with a negative PCR at baseline and 21.9% (61
219 of 279) participants with a positive PCR at baseline met the primary outcome criteria. The intervention
220 was ineffective, regardless of the PCR result at baseline.

221 We observed an overall increased risk of Covid-19 with increasing viral load of the participant at baseline
222 (Fig. 2A) and increasing viral load of the index case (Fig. 2B). The viral load of contacts who developed
223 confirmed Covid-19 increased 4 log₁₀ copies/mL throughout the follow-up, whereas that of contacts
224 without Covid-19 remained unchanged (Fig. 2C). Pre-specified subgroup analysis of the primary outcome
225 did not reveal between-group differences in the risk of Covid-19 according to the viral load of the
226 participant at baseline, the viral load of the index case, the length of exposure, or the place of contact (Fig.
227 3).

228 The survival analysis of the time to the primary outcome showed similar patterns in the two arms
229 regarding confirmed Covid-19 onset from enrolment (median 14.0 vs. 14.0 days in the control and
230 intervention arms, respectively; HR 0.9 [95%CI 0.6–1.5]) and from exposure (median 18.0 vs. 18.0 days;
231 HR 1.0 [0.6–1.6]) (Fig. S3).

232 *SECONDARY OUTCOMES*

233 Of the 2,000 participants who tested negative for SARS-CoV-2 in the baseline PCR, 364 (18.2%) either
234 became PCR positive or developed symptoms compatible with Covid-19 throughout the follow-up period
235 (secondary outcome, Table 2), without differences between study arms (17.8%, 185/1,042 control vs.
236 18.7%, 179/958 intervention; RR 1.04 [95%CI 0.77 1.41]). The virus-specific IgG/IgM positivity was
237 higher in the intervention arm than in the control arm (6.7%, 70/1,042 control vs. 10.4% 100/958). Of 125

238 participants who became PCR-positive during follow-up, 30 (24.0%) were seropositive on day 14 (Fig
239 S4).

240 *ADHERENCE AND SAFETY*

241 Full adherence for the trial intervention was 97.5% (1,268 of 1,300) in the control arm and 95.1% (1,138
242 of 1,1197) in the intervention arm. In the safety population, 77/1,300 (5.9%) participants in the control
243 arm and 671/1,197 (51.6%) in the intervention arm experienced at least one AE during 14 days of follow-
244 up (Table 3). The most frequent treatment-related AEs among participants given HCQ were
245 gastrointestinal (diarrhea, nausea, and abdominal pain) and nervous system disorders (drowsiness,
246 headache, and metallic taste) (Tables S4). Thirty-one SAE were reported, 17 in the control arm and 14 in
247 the intervention arm, none of them related to HCQ (Table S5). Six AEs of special interest were observed,
248 including five episodes of self-limited palpitations potentially related to treatment (Table S6). Relevant
249 safety data listings are provided in the Supplementary Appendix.

250

251 **DISCUSSION**

252 Postexposure prophylaxis with HCQ did not prevent Covid-19 disease or SARS-CoV-2 infection in
253 asymptomatic contacts exposed to a PCR-positive index case. In our cohort, the overall attack rate for the
254 PCR-confirmed symptomatic Covid-19 was 6.0%, excluding subjects that were not enrolled because had
255 symptoms before the baseline assessment. HCQ did not decrease the incidence of confirmed Covid-19
256 disease among contacts (6.2 vs. 5.7%). Our trial tested two possible effects of postexposure therapy:
257 prophylaxis in contacts with negative PCR at baseline, and preemptive therapy in contacts with positive
258 PCR at baseline (i.e., prevent progression of asymptomatic infection to disease). This dual scenario
259 mirrors a real-life setting, where the PCR result of people exposed to a known Covid-19 case is usually
260 not available immediately. Among PCR positive contacts at baseline (12% of subjects), the intervention
261 had no apparent efficacy as early preemptive therapy. Of note a baseline positive PCR result significantly

262 increased the risk of developing Covid-19 in our cohort, but a high proportion of participants with this lab
263 result (79%) did not go on to develop symptomatic disease, thus reinforcing the need to quarantine or to
264 increase testing of contacts even if asymptomatic. Also, of importance to the public health decision-
265 making is that high Covid-19 viral load ($>10^8$ log₁₀ copies/mL (SD) results in more risk of transmission to
266 contacts.

267 The intervention also did not reduce the transmission of SARS-CoV-2 (17.8% vs. 18.7%) or incidence of
268 seropositivity. Notably, the overlap of positive PCR and positive serology was low, which could be
269 related to both, the reported low rate of seroconversion in asymptomatic contacts²¹ or the higher risk of
270 false negative PCR result on the initial stage of infection.¹⁵ Regarding safety, we observed a higher
271 incidence of AE in the treatment group, albeit with low severity. This is an open-label study where the
272 psychological components in the treated group cannot be excluded. Furthermore, the side effects reported
273 were mainly at gastrointestinal level, while only five (0.3%) out of 1,479 events could be considered
274 cardiac, thus not confirming previously published data that raised safety concerns.²² The safety results
275 need to be interpreted considering the dose used, length of treatment, and the lack of ECG monitoring in
276 the study.

277 The strengths of this study are the use of PCR and viral load titration at baseline, at day 14, and
278 potentially when ill, and the measurement of viral load of the source index case to estimate risk of
279 transmission. In addition, we included elderly persons (e.g. ages >90 years of age) from nursing homes.
280 The study has some limitations. Unlike the common procedure in clinical trials, the informed consent
281 signature took place after cluster-randomization. Nevertheless, allocation was revealed to participants
282 after consent signature, therefore we believe the allocation concealment strategy was appropriate to
283 prevent study participants from choosing to participate or not to participate. Owing to the urgency, the
284 trial could not be masked with a placebo, which affected the rate of AE declared (AEs are not commonly
285 reported in the control, non-placebo group), but it did not affect the attrition numbers in the control arm.

286 However, it is worth mentioning that the laboratory staff who performed PCR tests remained unaware of
287 the allocation of each sample.

288 Despite the promising in-vitro results that placed HCQ among the leading candidates for Covid-19
289 treatment and prophylaxis,^{23–25} to date there is no strong argument to suggest that HCQ is effective. We
290 provide high-quality evidence on the lack of efficacy of postexposure prophylaxis therapy with HCQ to
291 prevent Covid-19 disease or SARS-CoV-2 infection. The data presented in this report is particularly
292 valuable for the scientific community and policymakers involved in controlling the pandemic at the
293 population level. Our findings encourage directing efforts to other antiviral candidates for postexposure
294 prophylaxis.

396

397

398 **Figure 1.** Flow diagram of individual selection and allocation.

399

400 Legend. The safety population (n=2,497; 1,300 in the control arm and 1,197 in the intervention arm)
401 included all individuals in the ITT population (except 28 not receiving any dose of study medication) plus
402 211 participants that received medication but were excluded from ITT because of screening-failure, or
403 missing PCR results on Day 14.

404

405 **Figure 2.** Association of baseline viral load of participants and viral load of their index case with
406 breakthrough Covid-19 (ITT population)

407 Legend. Panels A and B show the association of the participant's viral load at baseline (A) and viral load
408 of the index case (B) with the likelihood of developing PCR-confirmed symptomatic Covid-19 in the
409 overall intention-to-treat population (aggregated data for the control and intervention arms). The dots are
410 participants with (=1) or without (=0) the primary outcome of PCR-confirmed Covid-19. Panel C shows
411 the viral load increase from baseline in participants who developed or did not develop Covid-19 (details
412 are provided in Table S2, Supplementary Appendix).

413

414 **Figure 3.** Subgroup analyses for the primary outcome according to risk of exposure factors (ITT
415 population)

416

417 **Tables**

418 **Table 1.** Baseline characteristics of study participants (contacts) included in the intention-to-treat
 419 population (N=2314).
 420

	Control arm (N=1,198)	Intervention arm (N=1,116)
Individuals' characteristics		
Age (years), <i>mean (SD)</i>	48.7 (19.3)	48.6 (18.7)
Gender (female), <i>n (%)</i>	875 (73.0%)	813 (72.8%)
PCR result at baseline, <i>n (%)</i> (N=2279) *		
Undetectable (< 10 ⁴ copies/mL)	1042 (88.5%)	958 (86.9%)
10 ⁴ -10 ⁶ copies/mL	88 (7.5%)	78 (7.1%)
10 ⁷ -10 ⁹ copies/mL	42 (3.6%)	58 (5.3%)
10 ¹⁰ -10 ¹² copies/mL	5 (0.4%)	8 (0.7%)
Coexisting disease		
None	547 (45.7%)	480 (43.0%)
Cardiovascular disease	178 (14.9%)	130 (11.6%)
Respiratory disease	47 (3.9%)	64 (5.7%)
Metabolic disease	94 (7.8%)	99 (8.9%)
Nervous system disease	170 (14.2%)	170 (15.2%)
Characteristics of clusters		
Number of days of exposure before enrollment, <i>median (IQR)</i>	4.0 (3.0, 6.0)	4.0 (3.0, 6.0)
Number of days of exposure before the intervention, N (%)		
≤3 days	411 (34.3%)	440 (39.4%)
4-6 days	668 (55.8%)	551 (49.3%)
≥7 days	119 (9.9%)	125 (11.2%)
Size of clusters, <i>median (IQR)</i>	2.0 (1.0, 3.0)	2.0 (1.0, 3.0)
Viral load of the index case, <i>n (%)</i> (N=549)		
Undetectable (< 10 ⁴ copies/mL) †	47 (16.2%)	42 (16.2%)
10 ⁴ -10 ⁶ copies/mL	85 (29.3%)	68 (26.3%)
10 ⁷ -10 ⁹ copies/mL	125 (43.1%)	129 (49.8%)
10 ¹⁰ -10 ¹² copies/mL	33 (11.4%)	20 (7.7%)
Type of contact with index case, <i>n (%)</i>		
Household contact	338 (28.2%)	302 (27.1%)
Healthcare worker	130 (10.9%)	131 (11.7%)
Nursing home worker	584 (48.7%)	550 (49.3%)
Nursing home resident	160 (13.4%)	133 (11.9%)
Routine use of mask, <i>n (%)</i> ‡		
Yes	825 (68.9%)	730 (65.4%)
No	256 (21.4%)	251 (22.5%)
NA	117 (9.7%)	135 (12.1%)
Sleeping in the same room as the index case, <i>n (%)</i>		
Yes	66 (5.51%)	78 (6.99%)
No	951 (79.4%)	834 (74.7%)
NA	181 (15.1%)	204 (18.3%)

421 **IQR:** interquartile range (i.e., 25th and 75th percentiles). **NA:** not available. **SD:** standard deviation.
 422

423 * Baseline PCR result was not available for 21 participants in the control arm and 14 participants in the intervention
424 arm.

425 † Pre-screening PCR was positive at the designated hospital lab prior to enrollment, but the result was negative
426 (undetectable < 10⁴ copies/mL) at the research lab from the swab collected on day 1.

427 ‡ Routine use of mask refers to use at the time of exposure.

428

429

430 **Table 2.** Outcomes of hydroxychloroquine prophylaxis against Covid-19 (intention-to-treat population).
431

	Control arm	Intervention arm	
	Events (%)	Events (%)	RR* (95% CI)
Primary outcome	N=1198	N=1116	
Overall (N = 2,314)			
PCR confirmed symptomatic Covid19	74 (6.2%)	64 (5.7%)	0.89 (0.54, 1.46)
Clinical and laboratory criteria	60 (5.0%)	49 (4.4%)	
Hospital or vital records criteria	14 (1.2%)	15 (1.3%)	
PCR (-) at baseline (N =2000)	N=1042	N=958	
PCR-confirmed symptomatic Covid19	45 (4.3%)	29 (3.0%)	1.45 (0.73, 2.88)
Clinical and laboratory criteria	37 (3.6%)	24 (2.5%)	
Hospital or vital records criteria	8 (0.8%)	5 (0.5%)	
PCR (+) at baseline (N=314)	N=156	N=158	
PCR-confirmed symptomatic Covid19	29 (18.6%)	35 (22.2%)	0.96 (0.58, 1.58)
Clinical and laboratory criteria	23 (14.7%)	25 (15.8%)	
Hospital or vital records criteria	6 (3.9%)	10 (6.3%)	
Secondary outcomes (N= 2,000) †	N=1042	N=958	
Covid19 either symptomatically compatible or PCR positivity regardless of symptoms	185 (17.8%)	179 (18.7%)	1.04 (0.77, 1.41)
Laboratory criteria ‡	67 (6.4%)	58 (6.1%)	
Clinical criteria □	150 (14.4%)	144 (15.0%)	
Hospital or vital records criteria	8 (9.7%)	5 (0.5%)	
Serology positivity on day 14	91 (8.7%)	137 (14.3%)	1.6 (0.96, 2.69)
IgM positivity	70 (6.7%)	100 (10.4%)	
IgG positivity	82 (7.9%)	118 (12.3%)	

432

433 **RR:** Risk ratio. **CI:** confidence interval.

434 * Risk ratios are adjusted for contact-level variables (age, gender, region, and time of exposure).

435 † Excluding PCR positive at baseline.

436 ‡ PCR confirmed either symptomatic or asymptomatic.

437 □ Symptoms compatible with Covid-19 regardless of PCR result

438 The components of the primary and secondary outcomes are not mutually exclusive.

439

440

441

442 **Table 3.** No. of subjects experiencing at least one AE (Safety population).

	Control arm N=1,300	Intervention arm N=1,197	P-value
Reported full adherence to trial intervention	1,268 (97.5%)	1,138 (95.1%)	
Adverse events			
Any AE	77 (5.9%)	671 (51.6%)	<0.001
Cardiac disorder (palpitations)	1 (0.1%)	5 (0.4%)	
Gastrointestinal disorder (diarrhea, abdominal pain, and vomiting)	33 (2.5%)	510 (42.6%)	
Nervous system disorder (headache, taste change, dizziness)	32 (2.5%)	260 (21.7%)	
General disorder (myalgia, fatigue, malaise)	10 (0.8%)	103 (8.6%)	
Intensity			<0.001*
Grade 1	44 (3.4%)	573 (44.1%)	
Grade 2	14 (1.1%)	68 (5.2%)	
Grade 3	2 (0.2%)	13 (1.0%)	
Grade 4	10 (0.8%)	11 (0.8%)	
Grade 5	7 (0.5%)	6 (0.5%)	
Serious AE †	17	14	
Hospitalization	12	11	
Deaths	8	5	
Treatment-related Serious AE	0	0	
AE of special interest (cardiac) ‡	1	5	

443
444 * overall p-value for grading
445 † None of the serious adverse events (SAE) were adjudicated as related to HCQ by the pharmacovigilance
446 consultants.
447 Death and hospitalization were not mutually exclusive; five deaths occurred at the hospital while other participants
448 died at a nursing home.
449 ‡ Cardiac disorders were all palpitations episodes; 3 of 5 events in the intervention arm were adjudicated as possibly
450 related to the study drug by the independent pharmacovigilance consultants. Details are provided in Table S6
451 (Supplementary material).
452
