## **ABSTRACT**

Klotho-VS heterozygosity (KL-VS<sup>het</sup>) is associated with reduced risk of Alzheimer's disease (AD). However, whether KL-VS<sup>het</sup> is associated with lower levels of pathologic tau, i.e. the key AD pathology driving neurodegeneration and cognitive decline, is unknown. Here, we assessed the interaction between KL-VS<sup>het</sup> and levels of beta-amyloid, a key driver of tau pathology, on the levels of PET-assessed neurofibrillary tau in 354 controls and patients within the AD continuum. KL-VS<sup>het</sup> showed lower cross-sectional increase in tau-PET per unit increase in amyloid-PET when compared to that of non-carriers. This effect of KL-VS<sup>het</sup> on tau-PET showed a tendency to be stronger in Klotho mRNA-expressing brain regions mapped onto a gene expression atlas. KL-VS<sup>het</sup> was related to better memory functions and this association was mediated by lower tau-PET. Amyloid-PET levels did not differ between KL-VS<sup>het</sup> carriers versus non-carriers. Together, our findings provide evidence for a protective role of KL-VS<sup>het</sup> against tau pathology and tau-related memory impairments in elderly humans at risk of AD dementia.

## INTRODUCTION

Klotho is a transmembrane protein that has been associated with enhanced longevity and better brain health in aging<sup>1,2</sup>. Klotho is expressed primarily in the kidney and brain, where it has been implicated in a number of vital cellular functions (for review see<sup>3</sup>). Loss-of-function mutations in transgenic mice are associated with reduced Klotho protein expression, accelerated aging phenotypes and dramatically shortened life span<sup>1,4</sup>. In humans, two variants in the KLOTHO gene (KL, 13q13.1), rs9536314 (F352V) and rs9527025 (C370S) form a functional haplotype. Carrying one copy, but not two copies of the KL-VS haplotype, referred to as KL-VS heterozygosity (KL-VS<sup>het</sup>), has been previously linked to increased Klotho levels in the blood<sup>5,6</sup>. KL-VS<sup>het</sup> occurs in about 20-25% of the population<sup>5</sup> and is associated with higher cognitive performance across the adult life span<sup>5,7-9</sup>, larger fronto-temporal grey matter volume in cognitively normal individuals<sup>8</sup> and lower mortality<sup>6,10</sup>. Together, these results suggest a crucial role of Klotho in the maintenance of cognitive abilities and brain integrity during aging. Beyond the protective role of Klotho in normal aging, recent studies suggest an association between Klotho and reduced risk of Alzheimer's disease (AD)<sup>11</sup>, the most frequent cause of dementia in the elderly<sup>12</sup>. A recent meta-analysis reported that KL-VS<sup>het</sup> was associated with reduced AD dementia risk and cognitive decline in elderly individuals carrying the ApoE  $\epsilon$ 4 allele<sup>13</sup>, i.e. the strongest genetic risk factor for AD dementia possibly through elevated levels of primary AD pathology including cortical beta-amyloid (A $\beta$ ) aggregation<sup>14,15</sup>. Importantly, KL-VS<sup>het</sup> was associated with reduced biomarker levels of A $\beta$  deposition in ApoE  $\epsilon$ 4 carriers<sup>16</sup> suggesting that KL-VS<sup>het</sup> may directly alter levels of primary AD pathology.

Yet, an open question is whether Klotho is associated with altered levels of fibrillary tangles containing pathologic tau, i.e. the key driver of disease progression in AD<sup>17</sup>. In the presence of A $\beta$  deposition, i.e. the earliest primary pathology in AD<sup>18,19</sup>, neurofibrillary tangles spread from the medial temporal lobe to higher cortical areas<sup>20</sup>. The progressive development of

neurofibrillary tangles in the presence of A $\beta$  pathology is closely associated with grey matter atrophy<sup>21-23</sup> and cognitive worsening<sup>20,24-26</sup> and is more predictive of such alterations than A $\beta$ <sup>27</sup>. Due to the high clinical relevance of tau pathology, it is pivotal to understand whether the KL-VS<sup>het</sup> variant attenuates the accumulation of neurofibrillary tangles at a given level of A $\beta$  deposition, and thus cognitive decline in AD. Studies in mouse models of A $\beta$  and accelerated aging reported that enhancing Klotho expression was associated with reduced A $\beta$  burden and phosphorylated tau<sup>11,28</sup>, although conflicting results were reported as well<sup>29</sup>. However, these mouse models fail to develop neurofibrillary tangles in the presence of A $\beta$  and thus only incompletely recapitulate AD-specific tau pathology in humans.

Here, we examined whether KL-VS<sup>het</sup> attenuates the association between higher A $\beta$  and higher fibrillar tau assessed via positron emission tomography (PET) in a group of 354 elderly asymptomatic and symptomatic individuals recruited within a large North American multicenter study on AD<sup>30</sup>. We found the KL-VS<sup>het</sup> variant to be associated with an attenuated increase in regional tau-PET at pathological levels of global amyloid-PET, suggesting that KL-VS<sup>het</sup> was protective against AD-related increase in neurofibrillary tangles. This effect was particularly pronounced in ApoE  $\epsilon$ 4 carriers. The strength of the KL-VS<sup>het</sup> effect on region-specific tau-PET levels showed a trend to be correlated with the regional expression pattern of KL in the brain<sup>31,32</sup> supporting the notion that the KL-VS<sup>het</sup> variant modulates regional accumulation of tau pathology. Importantly, KL-VS<sup>het</sup> was associated with higher memory performance and this effect was mediated by reduced tau-PET levels in KL-VS<sup>het</sup> carriers with elevated amyloid-PET burden. For A $\beta$ , we did not find the previously reported protective effect of KL-VS<sup>het</sup> against A $\beta$  pathology in the current sample, but confirmed this effect in a larger sample including all individuals with amyloid-PET but not necessarily tau-PET assessment available indicating that the effect size of KL-VS<sup>het</sup> on A $\beta$  was smaller than that on tau pathology. Overall, we show a protective role of KL-VS<sup>het</sup> against the development of tau

pathology and thus cognitive decline, suggesting that Klotho could be an attractive treatment target to slow the progression of AD.

## RESULTS

Detailed sample characteristics are presented in **Table 1**. Among the 354 participants (213 CN, 111 MCI, 30 ADD), there were 92 KL-VS<sup>het</sup> carriers and 262 non-carriers. Demographics (age, sex, education) or ApoE ε4 status did not differ between KL-VS<sup>het</sup> carrier and non-carrier groups (all  $p > 0.05$ ). Continuous values of global amyloid-PET uptake did not differ between KL-VS<sup>het</sup> carriers versus non-carriers ( $t(174.74) = 1.40$ ,  $p = 0.163$ ).

### **KL-VS heterozygosity attenuates effects of amyloid on tau accumulation**

In our main analysis, we tested the hypothesis that KL-VS<sup>het</sup> modifies the association between Aβ and tau pathology (both assessed by continuous measures of PET uptake). In a region-of-interest (ROI) based analysis we focused on tau-PET in the inferior temporal cortex (i.e. ROI of early Aβ-related tau pathology<sup>20,24,33-35</sup>) and whole-brain tau-PET levels. The results of a linear regression analysis showed a significant KL-VS<sup>het</sup> x amyloid-PET interaction effect on tau-PET levels in both the inferior temporal ROI (standardized beta = -0.57,  $p = 0.018$ , effect size measured by Cohen's  $f = 0.128$ ) and the global ROI (beta = -0.54,  $p = 0.030$ , Cohen's  $f = 0.118$ ). For both tau-PET ROIs, the increase in tau-PET as a function of rising global amyloid-PET was attenuated in KL-VS<sup>het</sup> carriers versus non-carriers (**Figure 1a, b**). This result suggests that the KL-VS<sup>het</sup> variant was protective against Aβ-associated accumulation of tau pathology. All analyses were controlled for main effects of the interaction terms, age, sex, diagnosis, education and ApoE ε4 carrier status. To determine whether our findings were driven by clinical diagnosis, we specifically repeated the analyses in 111 MCI patients (21 KL-VS<sup>het</sup> carriers and 90 non-carriers) and found comparable KL-VS<sup>het</sup> x amyloid-PET interaction effects on tau-PET

uptake (inferior temporal ROI:  $\beta = -1.06$ ,  $p = 0.021$ , Cohen's  $f = 0.230$ ; global ROI:  $\beta = -1.01$ ,  $p = 0.025$ , Cohen's  $f = 0.224$ ; **eFigure 1 in Supplement**). Previous studies have reported an ApoE- $\epsilon 4$ -genotype dependent effect of KL-VS<sup>het</sup> on amyloid PET<sup>16</sup>. Hence, we additionally explored whether ApoE  $\epsilon 4$  carriers showed a stronger protective effect of KL-VS<sup>het</sup> against tau accumulation than ApoE  $\epsilon 4$  non-carriers, controlling for age, sex, education, diagnosis and global amyloid-PET levels in the regression analyses. We found KL-VS<sup>het</sup> to be associated with lower tau-PET levels in ApoE  $\epsilon 4$  carriers for the global ROI ( $\beta = -0.15$ ,  $p = 0.032$ ) and at trend level for the inferior temporal ROI ( $\beta = -0.12$ ,  $p = 0.080$ ), whereas we found no main effect of KL-VS<sup>het</sup> in ApoE  $\epsilon 4$  non-carriers (global ROI:  $\beta = 0.02$ ,  $p = 0.711$ ; inferior temporal ROI:  $\beta = 0.01$ ,  $p = 0.817$ ; **eFigure 2 in Supplement**). Tested in the whole sample, the KL-VS<sup>het</sup>  $\times$  ApoE  $\epsilon 4$  interaction effect on tau-PET levels was not significant (global ROI:  $\beta = -0.09$ ,  $p = 0.135$ ; inferior temporal ROI:  $\beta = -0.09$ ,  $p = 0.108$ ).

### **Spatial match between KL mRNA expression and the effect of KL-VS heterozygosity on tau-PET**

In order to estimate the spatial overlap between regions of KL gene expression and regions for which the KL-VS<sup>het</sup>  $\times$  amyloid-PET interaction on tau-PET was significant, we obtained whole-brain mRNA expression levels of KL generated by post-mortem microarray assessments of six healthy brain donors and subsequently mapped to the Allen Brain Atlas<sup>31,32</sup>. We computed median scores of log<sub>2</sub> mRNA expression of KL across the six donors within 34 left-hemispheric regions of the Freesurfer-based Desikan–Killiany brain atlas<sup>36</sup>. We focused on the left hemisphere, since all donors had microarray assessment available for the left hemisphere and only two donors had assessment for the right hemisphere. Furthermore, we estimated the KL-VS<sup>het</sup>  $\times$  amyloid-PET interaction effect on tau-PET levels within the same 34 brain-atlas regions using the aforementioned regression model. Surface mapping of both the KL-VS<sup>het</sup>  $\times$  amyloid-

PET interaction effect (which were all in the same direction) and KL mRNA expression is displayed in **Figure 2a-d**. Spatial correlation analysis revealed an association at trend level ( $r = 0.34$ ,  $p = 0.049$ ; **Figure 2e**). This result suggests that regions with higher KL mRNA expression levels were more likely to display a stronger protective effect of KL-VS<sup>het</sup> on A $\beta$ -related increase in tau-PET. Visual inspection of the thresholded spatial maps indicated that those areas showing both a significant KL-VS<sup>het</sup>  $\times$  amyloid-PET interaction effect (**Figure 2b**) and high KL mRNA expression ( $\log_2 > 75^{\text{th}}$  percentile) (**Figure 2d**) were specifically located within the mesio-temporal and inferior temporal brain regions and the posterior cingulum.

### **Tau mediates the beneficial effect of KL-VS heterozygosity on memory**

Next, we assessed whether KL-VS<sup>het</sup> is beneficial for memory functions via lowering tau pathology. Because the interaction effect of KL-VS<sup>het</sup>  $\times$  amyloid-PET on tau-PET levels showed that the protective role of KL-VS<sup>het</sup> against tau accumulation was stronger at higher levels of amyloid-PET, we restricted our analysis to participants who displayed elevated global amyloid-PET levels. The optimal amyloid-PET SUVR threshold for sample selection was identified in our data as SUVR > 1.0 including 67 KL-VS<sup>het</sup> carriers and 191 non-carriers (see Methods for more details on sample selection). We used mediation analysis with 10,000 bootstrapping iterations in order to test whether KL-VS<sup>het</sup> is associated with better memory in individuals with elevated A $\beta$  burden and whether this effect is mediated via reduced global tau-PET levels. Memory performance was measured by an established composite score based on participant's results across multiple different memory tests (ADNI-MEM)<sup>37</sup>. The mediation analysis was controlled for age, sex, education, diagnosis, ApoE  $\epsilon$ 4 status and global amyloid-PET levels. Supporting our hypothesis, we found KL-VS<sup>het</sup> to be associated with higher ADNI-MEM scores (beta = 0.12,  $p = 0.029$ , Cohen's  $f = 0.137$ , **Figure 3**) and that this relationship was significantly mediated by lower tau-PET levels (bootstrapped average causal mediation effect: beta = 0.05, 95% confidence interval = 0.01 - 0.10,  $p = 0.008$ ). This result indicates that, in individuals with

an elevated amyloid burden, KL-VS<sup>het</sup> carriers showed less impaired episodic-memory abilities when compared to KL-VS<sup>het</sup> non-carriers due to lower tau-PET levels in KL-VS<sup>het</sup> carriers. A path model of the mediation analysis is shown in **Figure 4**.

In order to address the question of whether KL-VS<sup>het</sup> exerts a beneficial influence on memory via lowered neurofibrillary tau in the whole sample without stratification based on amyloid-PET levels, we estimated the interaction effect between KL-VS<sup>het</sup> and amyloid-PET on ADNI-MEM scores, with and without controlling for global tau-PET levels as a covariate. We reasoned that if the association between KL-VS<sup>het</sup> on cognition is mediated by tau-PET, the interaction between KL-VS<sup>het</sup> and amyloid-PET on cognition should be diminished when controlling for tau-PET. Without controlling tau-PET levels, we found a borderline significant KL-VS<sup>het</sup>  $\times$  amyloid-PET interaction effect on memory functions (beta = 0.42,  $p = 0.049$ , Cohen's  $f = 0.107$ ). Specifically, we observed that individuals with high amyloid-PET burden showed better cognitive performance when being KL-VS<sup>het</sup> carriers compared to non-carriers (**eFigure 3 in Supplement**). As hypothesized, the KL-VS<sup>het</sup>  $\times$  amyloid-PET interaction on memory no longer reached significance level when global tau-PET levels were controlled for (beta = 0.31,  $p = 0.139$ ).

### **Confirmation of the protective effect of KL-VS<sup>het</sup> against A $\beta$ accumulation in a larger sample**

A recent study found a protective influence of KL-VS<sup>het</sup> on longitudinal amyloid-PET in cognitively unimpaired ApoE  $\epsilon 4$  carriers aged between 60 and 80 years, but not in ApoE  $\epsilon 4$  non-carriers or older participants<sup>13</sup>. In contrast to this earlier report, we did not find an age- or ApoE  $\epsilon 4$ -dependent KL-VS<sup>het</sup> effect on cross-sectional amyloid-PET levels acquired at the time of tau-PET assessment in the current sample (KL-VS<sup>het</sup>  $\times$  age interaction: beta = 0.02,  $p = 0.969$ , KL-VS<sup>het</sup>  $\times$  ApoE  $\epsilon 4$  interaction: beta = 0.02,  $p = 0.744$ ; KL-VS<sup>het</sup>  $\times$  age  $\times$  ApoE  $\epsilon 4$  interaction: beta = 0.39,  $p = 0.574$ ; **eFigure 4 in Supplement**). However, more subtle effects may have

been overlooked in the current more restricted sample of individuals undergoing both amyloid- and tau-PET. Therefore, in a supplementary analysis we included all participants with amyloid-PET (N=959) from ADNI, regardless of whether or not they underwent tau-PET assessment. We found a significant KL-VS<sup>het</sup> x age interaction effect on amyloid-PET which demonstrated that KL-VS<sup>het</sup> carriers in the lower age range (< 80 years) displayed lower amyloid-PET levels than non-carriers (beta=0.62, p=0.033, Cohen's f = 0.069, **eFigure 5a in Supplement**). As observed earlier, the beneficial effect of KL-VS<sup>het</sup> on amyloid-PET levels was driven by ApoE ε4 carriers rather than non-carriers (**eFigure 5bc in Supplement**). See **eTable 1 in Supplement** for detailed sample characteristics of the larger ADNI amyloid-PET sample compared to the current ADNI tau-PET sample. Thus, our results in the larger sample are consistent with those from Belloy et al.'s analysis on the effect of KL-VS<sup>het</sup> on amyloid-PET stratified by age and ApoE genotype while also showing that the effect size of KL-VS<sup>het</sup> on tau-PET is stronger than that on amyloid-PET.

## DISCUSSION

The heterozygous KLOTHO gene variant KL-VS<sup>het</sup>, has been previously associated with higher longevity and cognition performance in adulthood and reduced AD dementia risk<sup>13</sup>. We demonstrate that elderly KL-VS<sup>het</sup> carriers with elevated A $\beta$  burden, i.e. the earliest primary AD pathology, exhibited lower tau-PET levels when compared to those in KL-VS<sup>het</sup> non-carriers. The KL-VS<sup>het</sup> variant was associated with better memory performance, and this relationship was mediated by lower tau-PET levels, suggesting that lower levels of pathologic tau in the KL-VS<sup>het</sup> carriers explain the protective association between KL-VS<sup>het</sup> and memory performance. Although our findings do not implicate a causative mechanism of Klotho in AD, we provide evidence for a protective role of KL-VS<sup>het</sup> against tau pathology which is the key AD brain alteration linked to cognitive impairment.

To our knowledge, the current study is the first to date that evaluated the interaction between KL-VS<sup>het</sup> and A $\beta$  on tau accumulation and cognitive decline in humans. There is a growing literature on protective genetic variants in AD<sup>38-40</sup>, but only a few studies have reported genetic variants to be associated with lower tau pathology in AD<sup>41</sup>. For the KL-VS<sup>het</sup> variant, previous studies reported an association with reduced A $\beta$  accumulation in elderly ApoE  $\epsilon$ 4 risk-carriers<sup>13,16</sup>. We extend these previous findings by showing that the relationship between A $\beta$  accumulation and fibrillar tau is modulated by KL-VS<sup>het</sup>, such that lower local and global tau-PET levels were observed per unit increase of global amyloid-PET burden in KL-VS<sup>het</sup> carriers when compared to those in non-carriers. This is important because A $\beta$  deposition precedes the development of dementia symptoms by up to 20 years<sup>14</sup>, and is associated with enhanced production of tau and the development of neurotoxic neurofibrillary tangles<sup>42</sup>. The region showing the strongest interaction effect between KL-VS<sup>het</sup> and amyloid-PET on tau-PET was the inferior temporal gyrus (Figure 2a), a brain area that typically shows an early A $\beta$ -related increase in tau-PET<sup>24</sup> before elevated tau-PET levels extend to other higher cortical brain

areas<sup>20</sup>. The protective association between KL-VS<sup>het</sup> and tau-PET was present selectively in participants with abnormally elevated levels of amyloid-PET and in ApoE  $\epsilon$ 4 carriers. Together, these results support the notion that KL-VS<sup>het</sup> is associated with an AD-related rather than age-related reduction of tau pathology.

We found KL-VS<sup>het</sup> to be associated with better memory performance, mediated by the effect of KL-VS<sup>het</sup> on tau-PET. Our results are broadly consistent with those from studies on healthy aging, reporting a protective effect of KL-VS<sup>het</sup> on cognition<sup>5,8-10</sup>, and lower risk of conversion from cognitively normal to mild cognitive impairment or AD dementia in ApoE  $\epsilon$ 4 carriers<sup>13,16</sup>. Our findings suggest that the association between KL-VS<sup>het</sup> and lower neurofibrillary tau pathology is of central importance for the protective effect of KL-VS<sup>het</sup> against cognitive impairment. A previously reported absence of an association between KL-VS<sup>het</sup> and cognitive decline in asymptomatic participants with elevated levels of A $\beta$ <sup>43</sup> did not assess the presence of abnormal neurofibrillary tau, which may have hampered to detect an effect of KL-VS<sup>het</sup> on cognitive decline in subjects at risk of AD<sup>33</sup>.

Previous studies reported KL-VS<sup>het</sup> to be associated with lower amyloid-PET in ApoE  $\epsilon$ 4 carriers (but not in ApoE  $\epsilon$ 4 non-carriers), which was strongest in the age range between 60 and 80 years<sup>13,16</sup>. In our primary analysis we did not confirm age- or ApoE  $\epsilon$ 4-dependent effects of KL-VS<sup>het</sup> on tau-PET. By investigating a larger sample of all participants with available amyloid-PET regardless of the availability of tau-PET (N = 959), we were able to substantiate those earlier findings<sup>13,16</sup>. Specifically, we showed reduced amyloid-PET burden in younger KL-VS<sup>het</sup> carriers (< 80 years) and, in accordance with previous work, this association was mainly driven by ApoE  $\epsilon$ 4 carriers rather than non-carriers. Comparing effect sizes, Cohen's  $f$  = 0.069 for the effect of KL-VS<sup>het</sup> on amyloid-PET versus  $f$  = 0.118 for the effect on tau-PET, strengthens the important role of changes in tau pathology for understanding the role of Klotho in AD.

The mechanisms linking Klotho to tau pathology remain elusive. Klotho is a pleiotropic protein that has been implicated in multiple biological processes including insulin regulation<sup>4</sup>, growth factor functions, in particular of FGF23<sup>44</sup>, regulation of members of the redox system<sup>45</sup>, and calcium signaling<sup>46</sup>. One possibility of how the Klotho protein might be linked to reduced neurofibrillary tau is its involvement in autophagy<sup>47</sup>, a mechanism that is involved in the clearance of AD pathologies<sup>48</sup>. Lentiviral overexpression of Klotho protein in an APP-PS1 mouse model of A $\beta$  deposition reduced A $\beta$  plaque load in aged mice and rescued the impaired autophagy possibly by modulating the Akt/mTOR pathway<sup>11,49</sup>. Since APP-PS1 mice do not develop tau pathology, it remains, however, to be tested whether Klotho-induced autophagy reduces tau pathology. Those mechanistic explanations remain speculative at this point and the current work encourages future studies to investigate the mechanism that could underlie the protection Klotho exerts against the development of tau pathology.

Our findings of the spatial correspondence between the strength of the effect of KL-VS<sup>het</sup> on regional tau-PET and the spatial distribution of Klotho mRNA suggests a local effect of Klotho on the development of fibrillar tau especially in temporal brain areas. The result of the spatial correlation analysis was at trend level and call for replication. Nevertheless, it is worth noting that alternative splicing of the human Klotho mRNA results in both a membrane-bound and a secreted transcript of Klotho<sup>1,4</sup>, indicating that Klotho may act both in a cell-autonomous manner and as a humoral factor. Therefore, differences in gene expression in Klotho in the brain and/or different circulating levels of Klotho linked to KL-VS<sup>het5</sup> may influence the development of pathological tau<sup>11</sup>, but this link remains to be investigated.

Several caveats should be considered when interpreting the current results. Firstly, the human KL gene consists of three polymorphic variants. We decided to focus on the KL-VS haplotype given the existing evidence of its beneficial influence on A $\beta$  and cognition in both mice and humans<sup>5,8-10,13,50</sup>. While the second variant C1818T (rs564481) is located on the fourth exon and likely has no functional consequences itself, the third variant G395A (rs1207568) is located

in the promotor region and may be a potential regulatory site of KL. The two latter variants appear more frequent in Asian populations, where they have been linked to cardiovascular risk factors<sup>51</sup>. Related to the current research question, an investigation across three independent cohorts of oldest old Danes found different polymorphic variants of KL, besides KL-VS, to be associated with better cognitive functions<sup>7</sup>. It has yet to be proven whether these other KL variants also support resilience in AD. Another caveat is that we did not measure Klotho protein levels in the serum or CSF. Circulating levels of Klotho decrease during aging<sup>52</sup> and are associated with cognitive performance<sup>5</sup> and grey matter volume<sup>53</sup> in cognitively unimpaired individuals. In patients with AD, CSF levels of Klotho are reduced<sup>50</sup>, where the experimental reversal of reduced Klotho expression in transgenic mouse models exerted beneficial effects on A $\beta$  and cognition<sup>8,11,28</sup>. While the KL-VS<sup>het</sup> variant has been associated with higher circulating levels of Klotho<sup>53</sup>, it remains to be investigated whether the association between KL-VS<sup>het</sup> and pathological tau are mediated by higher protein levels in the CSF and brain tissue.

In summary, due to the high clinical relevance of tau accumulation and mixed results from trials on A $\beta$  immunization<sup>54</sup>, strategies for targeting tau pathology are moving into focus<sup>55</sup>. Our findings revealed a protective effect of KL-VS<sup>het</sup> against tau accumulation which particularly manifested in at-risk individuals, where lower tau pathology was related to better cognitive functions. Our results encourage future studies on enhancing Klotho proteins levels as a therapeutic intervention to slow down the development of tau pathology and dementia in AD.

## **MATERIALS & METHODS**

### **Sample**

354 participants were selected from ADNI phase 3 (ClinicalTrials.gov ID: NCT02854033) based on the availability of KL-VS and ApoE  $\epsilon$ 4 genotyping, T1-weighted MRI,  $^{18}\text{F}$ -AV1451 tau-PET and  $^{18}\text{F}$ -AV45 amyloid-PET. MR and PET imaging had to be acquired during the same study visit. The two single nucleotide polymorphisms (SNPs) for KL-VS (rs9536314 for F352V, rs9527025 for C370S) and ApoE (rs429358, rs7412) were genotyped using DNA extracted by Cogenics from a 3 mL aliquot of EDTA blood. Participants were assigned to the heterozygous KL-VS group when they carried 1, but not 2, copies of the KL-VS haplotype. ApoE  $\epsilon$ 4 carriers were defined as individuals carrying at least one  $\epsilon$ 4 allele. Clinical classification was performed by the ADNI centers, dividing participants into cognitively normal (CN, MMSE>24, CDR=0, non-depressed), mild cognitively impairment (MCI; MMSE>24, CDR=0.5, objective memory-loss on the education adjusted Wechsler Memory) or AD dementia (ADD;  $19 < \text{MMSE} < 24$ , CDR=0.5-1.0, NINCDS/ADRDA criteria for probable AD are fulfilled). All participants provided written informed consent and all work complied with ethical regulations for work with human participants.

### **MR and PET acquisition and preprocessing**

All imaging data was downloaded from the ADNI Ioni image archive (<https://ida.ioni.usc.edu>). Structural T1-weighted images were acquired on 3T scanners using a 3D MPRAGE sequence with 1mm isotropic voxel-size and a TR=2300ms (detailed scan protocols can be found on: <https://adni.ioni.usc.edu/wp-content/uploads/2017/07/ADNI3-MRI-protocols.pdf>). Structural images were processed using Freesurfer (version 5.3.0) and parcellated according to the Desikan-Killiany atlas<sup>56</sup>.

Tau-PET was assessed in 6×5 min blocks 75 min after intravenous bolus injection of <sup>18</sup>F-AV1451 Flortaucipir. Amyloid-PET scans were obtained during 4×5 min time frames measured 50-70 min post-injection of <sup>18</sup>F-AV45 Florbetaben. For both AV1451 tau- and AV45 amyloid-PET we downloaded partially preprocessed data (<http://adni.loni.usc.edu/methods/pet-analysis-method/pet-analysis/>).

All PET images were coregistered to the corresponding T1-weighted image to make use of Freesurfer-derived masks in participants' high resolution, native space. Standard uptake value ratio (SUVR) scores were obtained by normalizing tau-PET images to the inferior cerebellar grey matter and amyloid-PET images to the whole cerebellar grey matter, following previous recommendations<sup>57</sup>.

### **Tau- and amyloid-PET regions of interest**

For the analyses of tau-PET, we extracted mean SUVR scores from bilateral inferior temporal gyri marking amyloid-associated spread of pathology to neocortical structures<sup>20,24,33-35</sup>. In addition, we assessed global tau-PET burden as the size-weighted mean SUVR score across all Freesurfer regions as described previously<sup>58</sup>, excluding hippocampus, thalamus and basal ganglia due to commonly reported tracer off-target binding<sup>59</sup>.

For the analysis of amyloid-PET images, we computed mean amyloid-PET levels from a global ROI spanning lateral and medial frontal, anterior and posterior cingulate, lateral parietal and lateral temporal regions. Mean SUVR from these regions was also used for sample stratification (see below).

### **mRNA expression levels of KL**

Regional gene expression was obtained from publicly available microarray measurements of regional mRNA expression based on post-mortem data from the Allen Brain Atlas (<http://human.brain-map.org>). The Allen Brain atlas is based on more than 60,000 microarray

probes collected from 3700 autopsy-based brain tissue samples from a total of 6 individuals aged 24–57 without known history of neurological or psychiatric diseases<sup>31,32</sup>. Microarray-based log<sub>2</sub> expression values of 20,737 genes within each of the 3700 samples were mapped back into MNI standard space by the Allen Brain Institute using stereotactic coordinates of the examined probes. The whole gene expression data has been recently mapped to the Freesurfer-based Desikan–Killiany atlas as median gene expression for probes falling within each of the 68 atlas ROIs<sup>36</sup>. Here, we specifically extracted median expression of KL mRNA within these Desikan–Killiany ROIs, to test a spatial correlation between KL expression and KL-VS<sup>het</sup> effects on local tau-PET uptake. Since microarray assessments and thus KL mRNA expression of all 6 Allen brain atlas subjects were available only for the left hemisphere (vs. 2 subjects for the right hemisphere), we restricted the analysis of KL mRNA expression data to the more robust estimates of the left hemisphere in line with previous studies<sup>60,61</sup>.

### **Neuropsychological assessment**

The ADNI neuropsychological test battery contains multiple indicators for memory functions, on which basis a composite score (ADNI-MEM) has been established<sup>37</sup>. ADNI-MEM summarizes test performance on the Rey Auditory Verbal Learning Test, elements from the AD Assessment Scale-Cognitive Subscale, word recall from the Mini-Mental State Examination (MMSE) and from the Wechsler Logical Memory Scale II.

### **Statistical Analysis**

Group demographics were compared between KL-VS<sup>het</sup> carriers versus non-carriers using Welch T-tests for continuous measures and Chi-squared tests for categorical measures.

In our main analysis, we tested whether KL-VS<sup>het</sup> moderates the relationship between amyloid- and tau-PET. To this end, two separate multiple linear regression analyses were used to estimate the interaction effects between KL-VS<sup>het</sup> and global amyloid-PET uptake. Our main analyses

included tau-PET ROIs of the inferior temporal as well as global tau-PET uptake as the dependent variables. For the KL mRNA analysis (see below), we computed the interaction effect within all 34 left hemispheric regions of the Desikan-Kiliany atlas. Besides the interaction term, regression models also included the main effects of KL-VS<sup>het</sup> and global amyloid-PET levels, controlled for the main effects of the interaction terms as well as potential confounding variables including age, sex, diagnosis, education and ApoE  $\epsilon$ 4 carrier status. To account for potential influences of clinical diagnoses, we ran the same analyses in the subsample of only MCI patients. Additional exploratory analyses were run to determine the influence of ApoE  $\epsilon$ 4 carrier status. In stratified analyses in either ApoE  $\epsilon$ 4 carriers or non-carriers we specifically tested for a main effect of KL-VS<sup>het</sup> on tau-PET uptake including age, sex, diagnosis, education and global amyloid-PET uptake as covariates. We also examined the interaction between KL-VS<sup>het</sup> and ApoE  $\epsilon$ 4 status on tau-PET levels in the whole sample taking the same covariates into account.

Next, we tested whether the favorable influence of KL-VS<sup>het</sup> on local tau-PET levels overlapped within those brain regions showing higher local KL mRNA expression levels. To this end, we determined KL mRNA expression using the Allen brain atlas data in all 34 left hemispheric Desikan–Killiany atlas regions and determined the KL-VS<sup>het</sup>  $\times$  amyloid-PET interaction effect on tau-PET uptake for corresponding anatomical regions. We then tested the ROI-to-ROI Pearson–Moment correlation between regional KL mRNA expression and the interaction effect test statistic.

In addition, we tested whether KL-VS<sup>het</sup> was associated with better memory functions, and whether this association was mediated by reduced tau-PET levels. Two alternative approaches were used to test this hypothesis. In the first approach, mediation analysis (causal *mediation* package implemented in *R*) was conducted in which KL-VS<sup>het</sup> variant was treated as predictor, global tau-PET levels as mediator and ADNI-MEM scores as outcome. Mediation analysis was performed in the largest subsample of individuals which showed a significant main effect of

KL-VS<sup>het</sup> on tau-PET levels. For sample selection, we computed the main effect of KL-VS<sup>het</sup> on tau-PET in different subsamples defined across a range of amyloid-PET thresholds (SUVR > 0.8-1.2). The optimal amyloid-PET threshold was identified as global SUVR > 1.0 (**eFigure 6 in Supplement**). Significance of the mediation effect was determined using 10,000 bootstrapped iterations, where each path of the model was controlled for age, sex, diagnosis, education, ApoE  $\epsilon$ 4 carrier status and global amyloid-PET levels. In an alternative approach, we estimated the interaction effect between KL-VS<sup>het</sup>  $\times$  amyloid-PET on cognitive functions. This analysis was performed in the entire sample. Importantly, the interaction analysis was once run without and once with controlling global tau-PET levels. We specifically hypothesized that if the beneficial effect of KL-VS<sup>het</sup> is dependent on lowering tau accumulation, then the interaction effect should be diminished in the tau-controlled analysis. Other covariates considered in the multiple regression models were age, sex, diagnosis, education and ApoE  $\epsilon$ 4 carrier status.

Lastly, we performed an exploratory analysis with the aim to confirm previously observed age-dependent associations between KL-VS<sup>het</sup> and lower amyloid-PET burden in ApoE  $\epsilon$ 4 carriers<sup>13</sup>. For this purpose, we tested for a KL-VS<sup>het</sup>  $\times$  age effect on global amyloid-PET levels in the current sample (N = 354) and in a larger ADNI sample (N = 959) including all participants with amyloid-PET assessment and KL-VS status (regardless of whether or not they underwent tau-PET assessment). Main effects of KL-VS<sup>het</sup> and age as well as sex, education and diagnosis were considered as covariates. In sensitivity analyses, we reran the interaction model in stratified groups of either ApoE  $\epsilon$ 4 carriers or non-carriers.

All statistical analyses were conducted with R statistical software (version 3.6.1). P-values were considered significant when meeting a two-tailed alpha threshold of 0.05.

## **Data availability**

The data that support the findings of this study were obtained from the Alzheimer's Disease Neuroimaging Initiative (ADNI) and are available from the ADNI database ([adni.loni.usc.edu](http://adni.loni.usc.edu)) upon registration and compliance with the data use agreement. A list including the anonymized participant identifiers of the currently used sample and the source file can be downloaded from the ADNI database (<http://adni.loni.usc.edu/>). The R-script used for the current study can be obtained from the first author upon request.

regions falling above the 75th percentile of KL mRNA expression. **e** Scatterplot depicting the positive association between ROI-based KL mRNA expression and  $KL-VS^{het} \times$  amyloid-PET interaction effect on regional tau-PET uptake. The solid grey line together with the shaded areas illustrate least-squares regression line  $\pm 95\%$  confidence interval.

*Figure 3*

**Figure 3 KL-VS heterozygosity effect on memory in individuals with elevated amyloid-PET burden**

Boxplot shows memory performance as a function of KL-VS<sup>het</sup> variant in individuals with a global amyloid-PET SUVR > 1.0. Blue and grey colour indicates individuals with heterozygous (N = 67) or non-heterozygous KL-VS alleles (N = 191). Memory was measured by an established composite score, ADNI-MEM, based on test performance across multiple different memory tests<sup>37</sup>. Statistical result of the main effect of KL-VS<sup>het</sup> on memory was derived from multiple linear regression analysis, controlled for age, sex, diagnosis, education and ApoE ε4 carrier status.

*Figure 4*

**Figure 4 Lower Tau-PET levels mediate beneficial effect of KL-VS heterozygosity on memory in individuals with elevated amyloid-PET burden**

Path diagram of the mediation model (assessed only in individuals with global amyloid-PET SUVR > 1.0, N = 258), showing that the association between KL-VS<sup>het</sup> and better memory performance is mediated via lower global tau-PET uptake. Memory is measured by ADNI-MEM, i.e. an established memory composite score<sup>37</sup>. Path-weights are displayed as standardized beta values. All paths are controlled for age, sex, diagnosis, education, ApoE ε4 carrier status and continuous global amyloid-PET levels. Effects are reported at \*p<0.05, \*\*p<0.01 and \*\*\*p<0.001. Significance of the indirect effect was determined using bootstrapping with 10,000 iterations as implemented in the *mediation* package in *R*.
