Keywords: Turner syndrome, recombinant human growth hormone, height growth, thyroid autoimmunity

1 **Abstract**

2 **Introduction:** Short stature and thyroid autoimmunity are among the most common traits in
3 Turner syndrome (TS). Recombinant human growth hormone (rhGH) treatment benefits
4 height growth in Turner syndrome individuals when applicable. This study aims to investigate
5 the association of thyroid autoimmunity and the response to rhGH treatment in Turner
6 Syndrome patients.

7 **Methods:** Medical records of 494 patients with TS were reviewed. Among 126 patients who
8 regularly tested for thyroid autoantibodies, 108 patients had received rhGH treatment. Clinical
9 characteristics, including karyotype and the presence of autoimmune thyroid diseases, as well
10 as rhGH treatment records were analyzed. Height velocity (HV) of patients with or without
11 thyroid autoimmunity was compared to assess the response to rhGH treatment. For patients
12 who received rhGH treatment and positive for thyroid autoantibodies, height velocity before
13 and after antibody presence was compared.

14 **Results:** 45XO monosomy presented in 36% (176/496) of patients. 42.1% of patients
15 (53/126) had elevated circulating anti-thyroid peroxidase antibody (TPOAb) and anti-
16 thyroglobulin antibody (TgAb). In 108 patients who received rhGH treatment, a negative
17 correlation was found between circulating TPOAb concentration and HV ($n=53$, $r = -0.276$,
18 $P<0.05$). For patients who developed thyroid autoantibodies during rhGH treatment, HVs
19 after thyroid autoantibody presence significantly decreased compared with HVs before
20 thyroid autoantibody detection ($n=44$, $p=0.0017$).

21 **Conclusions:** Our data suggested that in preadult TS patients who developed thyroid
22 autoantibodies during rhGH treatment, the response to rhGH is negatively associated with the
23 development of thyroid autoimmunity.

24

25 **Introduction**

26 Turner syndrome (TS) is one of the most common chromosomal diseases caused by lack of
27 one X chromosome or structurally abnormal X chromosome. The frequency of TS is
28 estimated as 25–50 per 100,000 females [1]. Clinical manifestations include growth
29 retardation, characteristic appearances, delayed puberty, incomplete sexual developments and
30 infertility [1].

31 Short stature is one of the main challenges in the clinical management of Turner syndrome.
32 The spontaneous growth of most TS patients lagged far behind normal females. Short stature
33 of TS patients was thought to be resulted from skeletal developmental defects [2] and could
34 be treated by recombinant human growth hormone (rhGH) [1]. Early initiation of recombinant
35 human growth hormone (rhGH) treatment is suggested to improve final height in TS patients
36 [1, 3-5]. It was reported that rhGH treatment could improve the average height velocity (HV)
37 from 2.9 cm/yr to 7.3 cm/yr in TS patients [3] and give an average final height gain of 7.2cm
38 [1, 6]. There are several factors associated with rhGH treatment outcome, including the age at
39 treatment start, duration of treatment, rhGH intake frequency and dosage [1, 3-5], and other
40 genetic-associated factors such as mid-parental height (MPH) [1]. Also, delayed bone age was
41 reported to be associated with better rhGH treatment outcome [5].

42 TS patients have increased risk of autoimmune disorders, such as inflammatory bowel
43 disease, juvenile rheumatoid arthritis, type 1 diabetes mellitus and especially, autoimmune
44 thyroid diseases (AITDs) [1]. TS patients are more likely to develop AITDs compared with
45 normal female throughout childhood and adulthood [7, 8]. The overall prevalence of AITDs
46 in TS patients is 38.6% and Hashimoto's thyroiditis (HT) is the most common subtype [9].
47 HT patients automatically develop anti-thyroid peroxidase antibody (TPOAb) and anti-
48 thyroglobulin antibody (TgAb) [9]. It was reported that TPOAb plays a main role for cell-

49 mediated cytotoxicity associated with thyroid autoimmunity, leading to diffuse lymphatic
50 infiltration, inflammation and dysfunction of the thyroid gland [10].

51 IGF-1 level is one of the major factors correlated with growth rate during rhGH treatment
52 [11]. An increasing correlation between autoimmune diseases and IGF-1 resistance had been
53 found recently [12]. The disruption of IGF-1 signaling pathway was reported in several
54 autoimmune diseases [12-14]. Antibodies against IGF-1 receptors (IGF-1R) were detected in
55 Graves' disease [12]. In patients with type 1 diabetes, tissue-specific mutation of IGF-1R was
56 found in pancreatic β cells [13]. In patients with rheumatic arthritis, IGF-1 or IgG collected
57 from patients could activate disease-derived synovial fibroblasts and CD4+ T cells suggested
58 that the peripheral tolerance of IGF-1R was broken [14]. Although the IGF-1 signaling
59 pathway disruption plays a role in autoimmunity, the association of thyroid autoimmunity and
60 the response to rhGH treatment in Turner syndrome has not been investigated yet.

61 In this single-center retrospective study, we analyzed the clinical characteristics and the height
62 velocity of TS patients with different thyroid autoimmunity status during rhGH treatment.

63

64 **Materials and Methods**

65 **Subjects**

66 A retrospective chart review was performed in 496 consecutive patients with Turner
67 syndrome (TS) followed up from 1999 to 2019 in Peking Union Medical College Hospital
68 [15]. The diagnosis of TS was confirmed by karyotype with 45XO, or other structural
69 abnormalities of the X chromosome. Among 126 patients who regularly tested TPOAb and
70 TgAb every 3-6 months, 108 had received rhGH treatment. Approval from the Institutional

71 Review Board of Peking Union Medical College Hospital was obtained for this study. All
72 data were de-identified before analysis.

73 **Anthropometrics**

74 Height and weight were measured by standard protocols in the early morning. BMI was
75 calculated as weight (kg) divided by height (m) squared. Height velocity (HV, cm/yr) was
76 calculated by average height growth (cm) per year to evaluate the response to rhGH treatment
77 [16, 17].

78 **Biochemical measurements**

79 Complete blood count, serum lipid profile, fasting blood glucose, uric acid, hepatic function
80 and renal function tests were all done in the central laboratory of the PUMCH by standard
81 methods. Serum concentration of free triiodothyronine (FT3), free thyroxine (FT4), thyroid-
82 stimulating hormone (TSH), TPOAb and TgAb were measured by the ADVIA Centaur XP
83 Immunoassay system (Siemens, Germany). Serum IGF-1 level was measured with a
84 chemiluminescent enzyme immunometric assay (Immulite 2000, Siemens Healthcare
85 Diagnostics, UK). All assays were performed in the department of clinical laboratory of
86 PUMCH.

87 **Statistical analysis**

88 Continuous data were represented by mean \pm standard deviation (SD). Data analyses were
89 performed with Microsoft Excel, version for windows (Microsoft Co. Ltd., Seattle, WA,
90 USA) and SPSS 24.0 software, version for Windows (SPSS Inc., Chicago, IL, USA).
91 Correlation of two variables was assessed with Pearson correlation coefficient (r). Differences

92 between two groups were detected using independent sample, two-sided student's t-test.

93 Results with $P < 0.05$ were considered statistically significant.

94

95 **Results**

96 **Demographic, clinical and biochemical characteristics**

97 As shown in Figure 1, medical charts of a total of 494 cases of TS patients were reviewed in
98 our center. Among them, 36% (176/494) had 45XO monosomy, 32% (158/494) was
99 chimeras, 10% (48/494) had X isochromosome, 13% (67/494) had partial deletion of X
100 chromosome and 9% (45/494) had other X chromosome structural abnormalities (Table 1).

101 Among these patients, 126 cases had repeated thyroid autoantibodies test every three to six
102 months during follow up and the general characteristics of these patients were summarized in
103 Table 2. The age of diagnosis of TS was 10.4 ± 4.1 yr in this population. 42.1% of patients
104 (53/126) had elevated TPOAb and TgAb and the first appearance of thyroid autoantibodies
105 were around 12.6 ± 4.9 yr. 57.9% of patients (73/126) were negative for thyroid autoantibodies.
106 Most patients developed TPOAb and TgAb simultaneously, and only one patient was only
107 TPOAb positive during follow-up. The TPOAb concentrations varied widely (0-5000U/ml)
108 among patients. Based on the presence of thyroid autoantibodies, patients were divided into
109 two groups. There was no difference in the initial demographic, clinical and biochemical
110 characteristics between the two groups of patients with or without thyroid autoantibodies
111 (Table 2).

112 Among 126 patients, 84.1% (106/126) had a height lagged below the third percentile of their
113 healthy peers. 85.7% (108/126) had received rhGH treatment, starting from 10.3 ± 3.3 years
114 old. The daily rhGH dosage was started from subcutaneous injection of 0.15 u/kg and titrated
115 according to serum IGF-1 concentration and growth velocity. 52.8% (57/108) patients started

116 rhGH treatment before 10 years old. In 53 patients who presented positive thyroid
117 autoantibodies, 44 accepted rhGH treatment from 10.1 ± 3.6 years old. While in 73 patients
118 who were negative for thyroid autoantibodies, 64 accepted rhGH treatment from 10.5 ± 3.2
119 years old in our clinic.

120 **Overall HV correlates to age, height, weight and BMI at treatment start point**

121 For patients who received rhGH treatment (n=108), the treatment start age, rhGH dosage and
122 the overall HV were not different between patients who developed thyroid autoimmunity and
123 who did not (Table 3).

124 Considering treatment start age, patients who started rhGH treatment before 10 years old had
125 better HV than patients who started rhGH treatment after 10 years old (7.55 ± 1.66 vs
126 5.21 ± 2.36 cm/yr, $P<0.0001$). A significant negative correlation between treatment start age
127 and height velocity was also detected (n=108, $r_s=-0.65$, $P<0.01$). For rhGH treated patients,
128 significant negative correlations were found between HV and treatment start height (n=108,
129 $r_s=-0.57$, $P<0.01$), start weight (n=108, $r_s=-0.46$, $P<0.01$) and start BMI (n=108, $r_s=-0.25$,
130 $P<0.05$).

131 **Thyroid autoimmunity status is associated with rhGH treatment response**

132 However, for patients who developed thyroid autoantibodies during rhGH treatment, HVs
133 after thyroid autoantibody presence significantly decreased compared with HVs before
134 thyroid autoantibody presence (7.51 ± 2.48 vs 5.51 ± 2.39 cm/yr, $P=0.0017$, Figure 2 and Table
135 4). For rhGH treated thyroid auto-Ab positive patients, HV is significantly negatively
136 correlated to treatment start age (n=44, $r_s=0.65$, $P<0.01$), start height (n=44, $r_s=-0.62$,
137 $P<0.01$), start weight (n=44, $r_s=-0.54$, $P<0.01$) and start BMI (n=44, $r_s=-0.38$, $P<0.05$). A

138 weak correlation was discovered between HV and serum TPOAb concentration for the same
139 group of patients (n=44, rs = -0.22, P=0.15).

140

141 **Discussion**

142 In this retrospective single-center study, the clinical characteristics including karyotype and
143 presence of autoimmune thyroid disease, as well as rhGH treatment records were analyzed in
144 a cohort of patients with Turner syndrome. Both the distribution of karyotype [1, 18] and the
145 average incidence of thyroid autoimmunity [8, 9, 18-20] are in consistence with previous
146 studies. Our data further suggested that for TS patients who developed thyroid autoantibodies
147 during rhGH treatment, the response to rhGH is negatively associated with the development
148 of thyroid autoantibodies.

149 TS patients have significant high risk of autoimmune thyroid diseases [1, 7-9, 18-20]. TS
150 children develop thyroid autoantibodies in a considerable high frequency and have higher
151 prevalence of AITDs compared with the general pediatric population [7-9, 19, 20]. The
152 morbidity of AITDs was found to increase significantly with age in TS patients and are absent
153 among very young patients [7-9, 19, 20]. However, elevation of peripheral blood thyroid
154 autoantibodies such as TPOAb and TgAb was always found at younger ages and priory to
155 clinical symptoms of AITDs in TS patients [7, 8]. Our study is consistent with previous
156 reports, with 42.06% of patients had elevated TPOAb and TgAb and the first appearance of
157 thyroid autoantibodies around 12.6 ± 4.9 yr. The abnormal X chromosome composition has
158 long been considered responsible for the increased risk of autoimmune disorders in TS
159 patients [1]. But results of clinical studies of karyotype and thyroid autoimmunity are
160 inconsistent [9, 18], and the underlying mechanism stayed unknown.

161 Plenty studies have discussed the factors associated with rhGH treatment outcome in TS
162 patients. It was suggested that patients with higher mid-parental height, younger bone age,
163 earlier treatment initiation, longer treatment duration before puberty induction and higher
164 rhGH dosage have better outcomes in final height [1]. These have also been demonstrated in
165 our data. Combination of ultra-low dose estrogen with rhGH had moderate benefit for height
166 growth [21]. Meanwhile, the correlation of karyotype to rhGH treatment outcome remained
167 obscure [22, 23] and the association of thyroid autoimmunity and the response to rhGH in TS
168 patients is under-investigated so far. In this study, the average rhGH treatment start age was
169 10.31 years old. Previous reviews also found that in the general TS population, the rhGH
170 treatment start age usually falls around 11.5 years old [9].

171 Our study firstly revealed that after presence of thyroid autoantibodies, height velocity
172 decreased significantly in TS patients during rhGH treatment. The interplay of autoimmunity
173 and childhood growth has been investigated from several aspects including the functional
174 crosstalk between immune system and IGF-1 signaling pathway [24-27], and energy tradeoff
175 between organ immune activity and growth [28-31].

176 The functional crosstalk of IGF-1 and immune regulation provides evidence from the aspect
177 of signaling transduction. The IGF-1 signaling pathway acts through IGF-1, IGF-1 receptor
178 (IGF-1R) and IGF binding proteins (IGFBPs) [24]. Relationship between immunity and IGF-
179 1 signaling was detailly reviewed [24]. The review suggested that IGF-1 signaling pathway
180 participate in the pathogenesis of autoimmune diseases in a complex and ambivalent manner
181 [24]. Autoimmunity usually lead to the disruption of IGF-1/IGF-1R signaling, especially by
182 producing autoantibodies against IGF-1R along with tissue-specific autoimmune targets [13,
183 24]. It was reported that in patients with GD [12, 14], T1DM [13] and RA [14], IGF-1R
184 autoantibody development, IGF-1 resistance and tissue overexpression of IGF-1R were

185 frequently observed as signals for the breakdown of peripheral tolerance of IGF-1R.
186 Meanwhile, it was recently reported that immune derived cytokine signals might directly
187 regulate certain IGF binding proteins (IGFBP), and immediately influence IGF-1 signaling
188 [25]. Thus, for TS patients who developed thyroid autoimmunity, tissue might encounter IGF-
189 1 resistance and have decreased response to rhGH treatment.

190 From the aspect of energy allocation, tissue immune activity is very energy costly and might
191 derive energy from other activities [29]. Especially, physical growth was found most likely to
192 be affected by the energy cost in tissue immunity during childhood [30-32]. A study had
193 revealed that increased tissue activity in immune functions at childhood would impair height
194 growth within a group of children living under high-pathogen, low-resource environments
195 [31]. Since developing autoimmunity suggested hyperactive of immune system, height growth
196 after thyroid autoimmunity might decrease compared with that of before in TS patients.

197 Recently, IGF-1 was found inhibitory of autoimmune diseases progression and inflammation
198 through binding IGF-1R on immune cells [12, 26, 33]. However, the protective role of IGF-1
199 signaling was only found in limited circumstances [12]. It was reported that recombinant
200 human insulin-like growth factor 1 (rhIGF-1) stimulates human and mouse regulatory T cells
201 (Tregs) in vitro, and the delivery of rhIGF-1 to mouse models with type-1 diabetes and
202 multiple sclerosis inhibits disease progression [26]. IGF-1 primed intestinal monocytes
203 acquired immune inflammation suppressive ability by secreting IL-10 [33]. The reciprocal
204 inhibition between autoimmunity and IGF-1 signaling pathway emphasized the importance of
205 balance in the immune system.

206 Considering the above clinical and experimental results, alterations in treatment strategy
207 should be made when supplementing rhGH to TS patients with autoimmune problems.
208 However, more detailed clinical studies should be conducted to make suggestions. The

209 decreased response might suggest increased treatment dose, but the IGF-1 level in TS patients
210 should not be excessive [1]. The increasing risk of glucose intolerance and diabetes in TS
211 patients alerted that rhGH treatment should be combined with a surveillance of IGF-1 level
212 and glucose metabolism [1]. Combine with the fact that IGF-1 resistance is common in
213 autoimmune diseases, we emphasize the importance of such surveillance especially in TS
214 patients with thyroid autoimmunity.

215 The main limitation of this study is that our data did not provide a causal link between thyroid
216 autoimmunity and response to rhGH treatment in TS patients since this is a retrospective
217 study. Prospective studies are needed to further reveal the cause effect of thyroid
218 autoimmunity in height growth among TS patients. At the same time, further studies to
219 investigate the molecular mechanisms underlying relationship between Turner syndrome,
220 thyroid autoimmunity and height growth are needed.

221 In summary, this study revealed a negative impact of thyroid autoimmunity on rhGH induced
222 height growth on TS patients. Meanwhile, we also emphasized that an early treatment of
223 rhGH significantly benefits patient height growth.

TS, turner syndrome; PUMCH, Peking Union Medical College Hospital

Table 2 Clinical and biochemical characteristics of 126 patients who regularly repeated thyroid autoantibodies tests

| Parameters | Thyroid auto-Ab positive (n=53) | Thyroid auto-Ab negative (n=73) | P value |
|------------------------------------|------------------------------------|------------------------------------|----------|
| Age (years) | 10.6±4.6 | 10.2±3.7 | 0.53 |
| Height (cm) | 124.8±19.3 | 124.3±14.6 | 0.60 |
| Weight (Kg) | 32.3±13.4 | 30.4±8.6 | 0.56 |
| BMI (kg/m ²) | 19.6±3.7 | 19.0±2.7 | 0.38 |
| FT3 (pg/ml) | 3.72±0.56 | 3.85±0.76 | 0.29 |
| FT4 (ng/dl) | 1.30±0.18 | 1.71±2.08 | 0.13 |
| TSH (μIU/ml) | 3.84±4.48 | 3.37±3.49 | 0.54 |
| Hypothyroidism ¹ (%) | 5.67 | 8.22 | 0.58 |
| Hyperthyroidism (%) | 1.89 | 1.37 | 0.82 |
| TPOAb (IU/ml) | 113.09±202.72 | undetected | <0.01*** |
| TgAb (IU/ml) | 414.12±969.79 | undetected | <0.01*** |

| | | | |
|---------------------------|---------------|---------------|----------|
| IGF-1 (ng/ml) | 439.65±189.71 | 483.35±213.75 | 0.32 |
| RBC (×10 ⁹ /L) | 4.77±0.39 | 4.76±0.41 | 0.89 |
| WBC (×10 ⁹ /L) | 6.62±1.87 | 6.52±1.96 | 0.80 |
| HGB (g/L) | 138.9±9.2 | 138.1±10.7 | 0.90 |
| PLT (×10 ⁹ /L) | 291.10±78.27 | 284.51±82.86 | 0.68 |
| Cr (μmol/L) | 48.2±9.2 | 47.6±9.9 | 0.74 |
| Uric Acid (μmol/L) | 321.2±79.2 | 325.8±75.4 | 0.77 |
| ALT (U/L) | 19.4±14.7 | 19.6±12.7 | 0.94 |
| AST (U/L) | 25.7±9.1 | 27.8±7.6 | 0.33 |
| TBiL (μmol/L) | 10.1±4.9 | 10.8±8.4 | 0.58 |
| Glu (mmol/L) | 4.82±0.53 | 4.94±0.42 | 0.21 |
| Na (mmol/L) | 139.6±1.7 | 139.9±1.7 | 0.37 |
| K (mmol/L) | 4.3±0.3 | 4.4±0.3 | 0.31 |
| Ca (mmol/L) | 2.44±0.10 | 2.45±0.09 | 0.39 |
| P (mmol/L) | 1.60±0.22 | 1.73±0.20 | 0.005*** |

| | | | |
|----------------|-------------|-------------|------|
| ALP (U/L) | 203.5±91.2 | 230.0±80.1 | 0.24 |
| TC (mmol/L) | 4.60±0.72 | 4.75±0.85 | 0.58 |
| TG (mmol/L) | 1.02±0.66 | 1.05±0.70 | 0.90 |
| HDL-C (mmol/L) | 1.44±0.33 | 1.15±1.60 | 0.19 |
| LDL-C (mmol/L) | 2.60±0.57 | 1.96±2.58 | 0.94 |
| FSH (IU/L) | 55.59±39.00 | 69.00±45.02 | 0.19 |
| LH (IU/L) | 12.06±9.85 | 14.80±11.15 | 0.29 |
| E2 (IU/L) | 23.29±20.52 | 24.76±16.35 | 0.75 |

Data are represented as mean ± SD (**: P<0.05, ***: P<0.01).

BMI, body mass index; rhGH, recombinant human growth hormone; FT3, free triiodothyronine; FT4, free thyroxine; TSH, thyroid stimulating hormone; TPOAb, thyroid peroxidase antibody; TgAb, anti-thyroglobulin antibody; IGF-1, insulin-like growth factor 1; RBC, red blood cell; WBC, white blood cell, HGB, hemoglobin, PLT, platelet; Cr, creatine; ALT, alanine aminotransferase; AST, aspartate aminotransferase; TBiL, total bilirubin; ALP, alkaline phosphatase; TC, total cholesterol; TG, triglyceride; HDL-C, high-density lipoprotein cholesterol; LDL-C, low-density lipoprotein cholesterol; FSH, follicle-stimulating hormone; LH, luteinizing hormone; E2, estrogen.

Table 3 Height velocity compared in rhGH treated TS patients with or without thyroid autoantibody

| | Thyroid auto-Ab positive | Thyroid auto-Ab negative | P value |
|----------------------------------|-----------------------------|-----------------------------|---------|
| Number of subjects | 44 | 64 | |
| Treatment start age (yr) | 10.1±3.6 | 10.5±3.2 | 0.89 |
| rhGH treatment dose (IU/kg/d) | 0.18 ±0.03 | 0.17± 0.04 | 0.59 |
| Height velocity (cm/yr) | 6.53±2.56 | 6.12±2.27 | 0.39 |

Data are represented as mean±SD (**: P<0.05, ***: P<0.01); rhGH, recombinant human growth hormone; TS, turner syndrome.

Table 4 Height velocity compared in rhGH treated TS patients before and after presence of circulating thyroid autoantibodies

| | rhGH treated thyroid auto-Ab positive | P value |
|--|--|---------|
|--|--|---------|

| | Before autoantibody presence | After autoantibody presence | |
|----------------------------------|---|--|----------|
| rhGH treatment duration (yr) | 1.5±1.5 | 1.0±1.1 | 0.10 |
| rhGH treatment dose (IU/kg/d) | 0.18 ±0.03 | 0.17±0.06 | 0.89 |
| Height velocity (cm/yr) | 7.51±2.48 | 5.51±2.39 | 0.0017** |

Data are represented as mean±SD (**: P<0.05, ***: P<0.01); rhGH, recombinant human growth hormone; TS, turner syndrome.

Figures

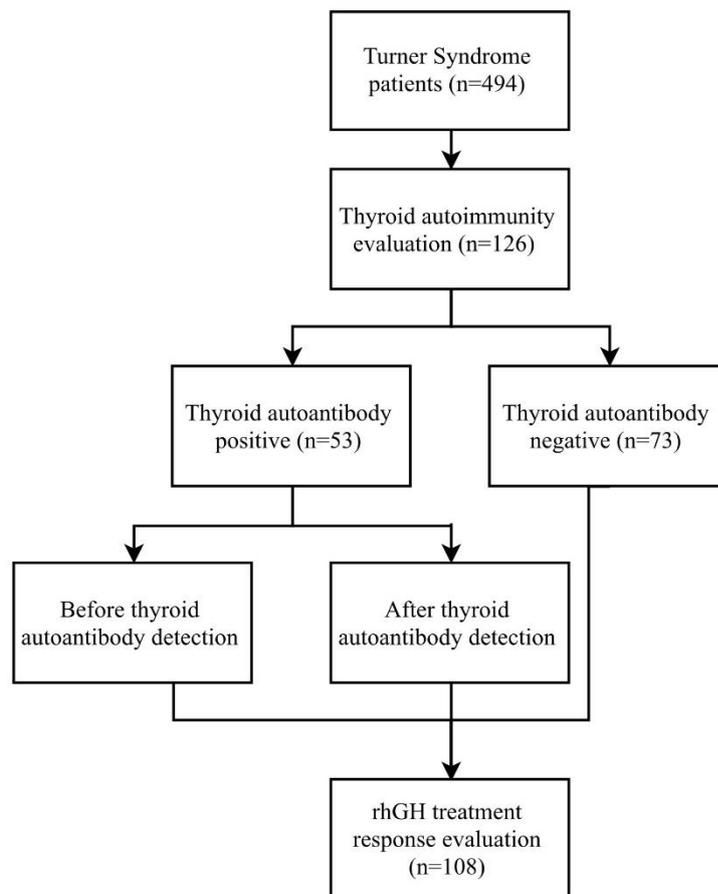

Figure 1. The flowchart of this study.

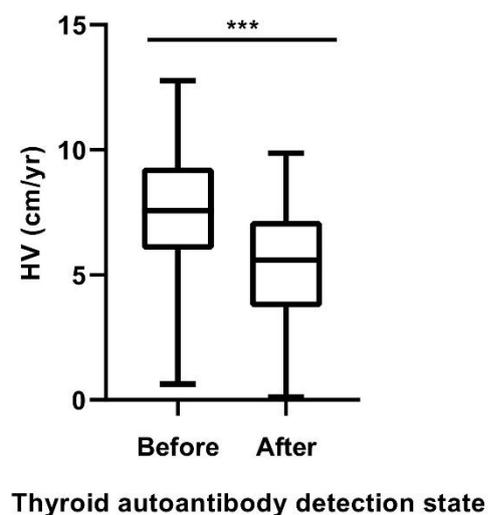

Figure 2. Height velocity (HV) in rhGH treated thyroid autoantibody positive TS patients before and after the detection of thyroid autoantibody. Patients have significantly lower HV after developing thyroid autoantibodies. Boxes indicate the first quartile and third quartile, whiskers indicated maximum and minimum values, means were represented by bars inside the boxes (n.s., not significant; **, $P < 0.05$; ***, $P < 0.01$).
