**ABSTRACT**

**Objective:** The objective of this review was to summarise the effects of different personal protective equipment (PPE) for reducing the risk of COVID-19 infection in health personnel caring for patients undergoing trauma surgery. The purpose of the review was to inform recommendations for rational use of PPE for emergency surgery staff, particularly in low resources environments where PPE shortages and high costs are expected to hamper the safety of healthcare workers (HCWs) and affect the care of trauma patients.

**Introduction:** Many healthcare facilities in low-and middle-income countries are inadequately resourced. COVID-19 has the potential to decimate these already strained surgical healthcare services unless health systems take stringent measures to protect healthcare workers from viral exposure.

**Inclusion criteria:** This review included systematic reviews, experimental and observational studies evaluating the effect of different PPE on the risk of COVID-19 infection in HCWs involved in emergency trauma surgery. Indirect evidence from other healthcare settings was considered, as well as evidence from other viral outbreaks summarised and discussed for the COVID-19 pandemic.

**Methods:** We conducted searches in the L·OVE (Living OVerview of Evidence) platform for COVID-19, a system that performs automated regular searches in PubMed, Embase, Cochrane Central Register of Controlled Trials (CENTRAL), and over thirty other sources. The risk of bias assessment of the included studies was planned with the AMSTAR II tool for systematic reviews, the RoBII tool for randomised controlled trials, and the ROBINS-I tool for non-randomised studies. Data were extracted using a standardised data extraction tool and summarised narratively. The Grading of Recommendations, Assessment, Development, and Evaluation (GRADE) approach for grading the certainty of the evidence was followed.

**Results:** We identified 17 systematic reviews that fulfilled our selection criteria and were included for synthesis. We did not identify randomised controlled trials during COVID-19 or studies additional to those included in the reviews that discussed other similar viral respiratory illnesses.

**Conclusions:** The use of PPE drastically reduces the risk of COVID-19 compared with no mask use in HCWs in the hospital setting. N95 and N95 equivalent respirators provided more protection and were found to halve the risk of COVID-19 contagion in HCWs from moderate and high-risk environments. Eye protection also offers additional security and is associated with reduced incidence of contagion. These effects apply to emergency trauma care. Decontamination and reuse appear as feasible, cost-effective measures that would likely help overcome PPE shortages and enhance the allocation of limited resources.
SUMMARY OF FINDINGS

There is high certainty that the use of N95 respirators and surgical masks are associated with a reduced risk of coronaviruses respiratory illness when compared with no mask use. In moderate to high-risk environments, especially in aerosol-generating procedures, N95 respirators are associated with a more significant reduction in risk of COVID-19 infection compared with surgical masks. Eye protection also reduces the risk of contagion. Decontamination of masks and respirators with ultraviolet germicidal irradiation, vaporous hydrogen peroxide, or dry heat is effective and does not affect PPE performance or fit.

(Figure 1: GRADE summary of findings)
INTRODUCTION

Many healthcare facilities in low-and middle-income countries are inadequately resourced. COVID-19 has the potential to decimate these already strained surgical healthcare services unless health systems take stringent measures to protect healthcare workers (HCWs) from viral exposure. A recent study showed that 15.6% of confirmed COVID-19 patients are symptomatic and that nearly half of patients with no symptoms at detection time will develop symptoms later. Furthermore, the preoperative evaluation of emergency trauma patients is limited. These factors impede and confound diagnostic triage. Improper infection prevention may create a ‘super-spreader’ event in a high-volume healthcare facility or reduce available personnel. Consequently, the infection control strategy of trauma surgery staff is a top priority.

To take care of patients, providers must first take care of themselves. Personal protective equipment (PPE) is paramount to protect health care workers from contracting the virus and becoming disease carriers. Basic recommended PPE for trauma surgery staff of high-income country facilities include: 1) a surgical mask or better for all personnel interacting with patients and in the OR (including cleaning staff); 2) N95 or better mask for all staff in close contact with the patients (<6 feet away); 3) PAPR for aerosolising and high-risk procedures (ear, nose, throat, thoracic, and transphenoidal neurosurgery operations); 4) universal testing of patients pre-operatively to enable appropriate PPE use, and 5) changing scrubs after every procedure. These recommendations are suitable for high-resource settings but are less feasible in low-resource settings. A rapid-turnaround survey of 40 healthcare organisations across 15 LMICs revealed that 70% lack PPE and COVID-19 testing kits, and only 65% of the respondents showed confidence in hospital staff’s knowledge about precautions to be taken to prevent COVID-19 infection among hospital personnel.

Some resource-adjusted recommendations include the use of cloth masks and bandanas. While innovative, their moisture retention, reusability, and filtration are considered very inferior to N95, and other masks. What is most needed is evidence guided recommendations for PPE use and COVID-19 screening in LMICs surgical systems where resources are either limited or unavailable. HCWs have been instructed to consider refraining from caring for patients in the absence of adequate PPE availability.

A preliminary search of PROSPERO, MEDLINE, the Cochrane Database of Systematic Reviews, and the JBI Database of Systematic Reviews and Implementation Reports was conducted, and no current or underway systematic reviews on the topic were identified.

The primary objective of the review was to summarise the effects of different personal protective equipment in reducing the risk of COVID-19 infection of health personnel caring for patients undergoing trauma surgery. The purpose of the review was to inform recommendations for the rational use of PPE in emergency surgery staff, particularly in low resources environments where PPE shortages and high costs are expected to hamper the safety of
HCWs and affect the care of trauma patients. A preliminary search of PROSPERO, MEDLINE, the Cochrane Database of Systematic Reviews, and the JBI Database of Systematic Reviews and Implementation Reports was conducted, and no current or underway systematic reviews on the topic were identified.

REVIEW QUESTIONS

We set to synthesise the available evidence on the effects of various personal protective equipment (PPE) in reducing the risk of COVID-19 infection of health personnel caring for patients undergoing trauma surgery. We were also interested in data on the costs associated with the use of PPE since it is a vital aspect to consider when generating recommendations for low-resources environments.

INCLUSION CRITERIA

Participants

We considered studies that included HCWs in emergency trauma surgery settings during the COVID-19 pandemic. Given the likelihood that reports on this specific population were scarce or even non-existent, we also included studies of HCWs in any procedural and in-hospital setting, such as the operating room, the emergency room, and critical care units. Furthermore, indirect evidence from other viral respiratory diseases (especially SARS and MERS) was considered if summarised and discussed regarding the COVID-19 pandemic.

Intervention(s)

Different types of PPE used while caring for patients in hospital settings (preferably in emergency surgery).

Comparator(s)

Comparators of interest were no PPE use and different types of PPE.

Outcomes

The primary outcome of interest was the risk of contagion to health personnel involved in the care of the described population during the COVID-19 pandemic, expressed as incidence, or with association measures such as risk ratios or odds ratio when compared to different PPEs or no-PPE. We were also interested in summarising evidence of costs associated with PPE use during the pandemic.

Types of studies

This review considered systematic reviews of experimental and observational studies, and experimental or observational studies if not included in systematic reviews that fulfilled population and intervention criteria. We also
included reports of costs associated with the use of PPE and reports on implementation strategies that could inform recommendations for low resource settings. Only studies published in English or Spanish were included. We included preprint studies identified in our search, but no ongoing studies were considered.

METHODS

We conducted a broad evidence synthesis (umbrella review) to summarise the effects of PPE on the risk of COVID-19 infection in healthcare workers (HCW) caring for patients in need of emergency surgery due to trauma. A protocol of this review following the PRISMA statement was registered in the International Prospective Registry of Systematic Reviews (PROSPERO; CRD42020198267). This review was conducted following the JBI methodology for systematic reviews of aetiology and risk.5

Search strategy

We conducted searches in the L·OVE (Living OVerview of Evidence) platform for COVID-19. The platform was consulted on Jul 27 2020, using the entries: 1) Prevention or treatment - Procedures – Protective measures - PPE + Population Filter: COVID19; 2) Prevention or treatment - Procedures – Protective measures -PE + Population filter: Health workers.

Information sources

The databases to be searched include the L·OVE (Living OVerview of Evidence) platform for COVID-19, a system that performs automated regular searches in PubMed, Embase, Cochrane Central Register of Controlled Trials (CENTRAL), and over thirty other sources. When compared to manual searches, this platform consistently identifies all the available studies associated with the terms of interest. It allows for a fast (automated) search that is easy to update - a crucial element given the urgent need to answer the research question rapidly and thoroughly.

Study selection

Following the search, all identified citations were collated and uploaded into EndNoteX9 (Clarivate Analytics, PA, USA). The citations were then imported into JBI SUMARI for the review process. Two independent reviewers examined titles and abstracts for eligibility. Full-text review verified fulfilment of selection criteria. All decisions taken during screening were documented and are outlined in this report with a list of excluded studies. Any disagreements that arose between the reviewers were solved by consensus. The results of the search are presented in a Preferred Reporting Items for Systematic Reviews and Meta-analyses (PRISMA) flow diagram (Figure 2).6
Assessment of methodological quality

Eligible studies were critically appraised by a reviewer and verified by a second reviewer using the AMSTAR tool. The risk of bias was assessed for only the primary outcome: infection of healthcare workers by COVID-19 or similar. The results of the critical appraisal are reported narratively and are considered for discussion of results.

All included studies, regardless of their risk of bias, underwent data extraction and synthesis.

Data extraction

Data were extracted from the included studies by a reviewer and verified by a second reviewer using a data extraction tool from JBI SUMARI. The data extracted include specific details about the populations, study methods, interventions, and outcomes of significance to the review question and specific objectives. Disagreements were solved by consensus.

Data synthesis

Studies were summarized narratively considering their scope, number of included studies, and risk of bias. Effect sizes from systematic reviews and individual studies not included in them are expressed as odds ratios (for dichotomous data) with their 95% confidence intervals.

Assessing certainty in the findings

The Grading of Recommendations, Assessment, Development, and Evaluation (GRADE) approach for grading the certainty of the evidence was followed. Grading the certainty of the evidence was not undertaken if adaptation from the identified reviews using the GRADE approach was considered complete and adequate. The certainty of the evidence was considered for interpretation and discussion of findings.

RESULTS

Study inclusion

The study selection process is illustrated in Figure 1. The described search identified a total of 258 records. After title and abstract screening, 78 studies were considered for full-text review, of which 59 were excluded. Reasons for exclusion were: wrong study design (n=29), wrong intervention (n=23), wrong outcomes (n=1), wrong language (n=5), wrong patient population (n=2). This left 19 studies for appraisal, extraction, and synthesis.
Appendix I shows a list of the 59 excluded studies, with reasons for their exclusion. In general, studies were excluded because they had a wrong study design (mostly narrative reviews, guideline recommendations, and case reports), wrong setting (non-hospital settings, community setting), and not reporting data related to COVID-19 contagion in healthcare workers.

Methodological quality

Tables 1-3 show the results of the critical appraisal of the methodological quality. Overall, the quality of the 19 included studies was assessed as moderate to high by JBI appraisal standards, and no disagreements occurred between the reviewers. Of the 17 included systematic reviews, nine fulfilled all 11 indicators of the critical appraisal tool,\(^ 69,70,72,75–77,79,81,82\) one fulfilled ten indicators,\(^ 68\) choosing not to perform risk of bias assessment given the rapid publication of the review; four fulfilled nine indicators,\(^ 4,80,83,84\) failing to report a risk of bias assessment and choosing not to combine studies for meta-analysis owing to study limitations and heterogeneity in study designs, comparisons, and analyses. Two fulfilled six indicators,\(^ 71,78\) having no method of study appraisal, no method of minimising errors in data extraction, failing to report a risk of bias assessment, and choosing not to combine studies for meta-analysis owing to study limitations and heterogeneity in study designs, comparisons, and analyses; and one fulfilled four indicators,\(^ 73\) for not reporting the indicators aforementioned in the previous studies in addition to a lack of future directives and recommendations for policy and clinical practice. All systematic reviews clearly stated the review question, applied appropriate inclusion criteria and search strategy.

Characteristics of included studies

The 17 included studies were systematic reviews,4,68–73,75,76,79–84. Appendix II provides details of the characteristics of the included studies. All but one study was published in 2020.79 Data extracted from reviews included thousands of participants from 35 different countries.

Ten of 17 systematic reviews evaluated the risk of contagion for respiratory viral infections,4,35,69–72,77,82 which six included outcome data for COVID-19 infection.4,69,72,75,77,78,82
Four systematic reviews,\textsuperscript{70,75,79,81} evaluate other respiratory pathogens such as seasonal influenza, SARS, H1N1, and MERS.

\section*{Review findings}

We did not identify comparative studies of PPE effect on the risk of COVID-19 contagion in the emergency surgery setting. We did identify observational studies of COVID-19 in HCW, as well as experimental and observational studies that also addressed this question in HCWs regarding other coronavirus epidemics (SARS and MERS epidemics) considered generalisable to the COVID-19 pandemic. Some studies also assessed and summarised evidence from other viral respiratory illnesses, such as H1N1 or influenza, and reported results consistent with those of the coronaviruses outbreaks.

A high-quality systematic review that evaluated the effect of physical distancing face masks and eye protection on preventing COVID-19 contagion included 172 studies, considering evidence from COVID-19, MERS, and SARS.\textsuperscript{72} The authors identified 30 comparative studies that focused on the effect of different masks and respirators on virus transmission in healthcare workers or patients and 13 studies that addressed the same effect for eye protection. They report that the use of a surgical mask compared with no face mask was associated with a considerable reduction in risk of contagion (OR= 0.33, 95\% CI= 0.17–0.61). An even larger effect was seen when comparing N95 and N95 equivalent respirators to no mask (OR= 0.04, 95\% CI= 0.004–0.30). Such estimates are based on studies, including a total of 12,817 participants. Adjusted and unadjusted studies were considered, and both estimates were consistent with the mentioned effect on contagion risk reduction when considering N95 or surgical/medical masks vs. no mask (adjusted OR= 0.15 (0.07 to 0.34); unadjusted RR 0.34 (95\% CI 0.26 to 0.45). Evidence for the precisely estimated reduction was rated as low by the authors, given some inconsistency and risk of bias. Nevertheless, the beneficial effect of mask protection was large, and they considered it of high certainty.\textsuperscript{72} They report that N95 had a stronger protective association compared with surgical masks or 12–16-layer cotton masks, and both N95 and surgical masks also had a stronger association with protection versus single-layer masks.

Regarding the use of eye protection, pooled analysis of 13 unadjusted and two adjusted studies suggested a reduced risk of contagion with eye protection compared with no eye protection (unadjusted: RR= 0.34, 95\% CI 0.22 to 0.52; adjusted OR= 0.22, 95\% CI 0.12 to 0.39). This review was considered pivotal due to the high number of included studies, the recent date of publication, and the adequacy of methods and reporting. Challenges reported in the studies included frequent discomfort, high resource use, less clear communication, and perceived reduced empathy of care providers by their patients.\textsuperscript{72}

A rapid systematic review that also addressed the effect of masks to prevent COVID-19 infection considered evidence from the current pandemic in addition to the SARS and MERS epidemics.\textsuperscript{4} The review reports a reduction
of risk of transmission associated with the use of masks in general. It suggests a more significant reduction associated with N95 respirators compared to surgical masks in the hospital setting (an effect seen for COVID-19 independently, as well as with the other coronaviruses outbreaks).

Other reviews considered evidence from viral respiratory illnesses, including influenza or H1N1, and report a beneficial effect of PPE (medical masks or N95 respirators) on contagion risk reduction. One of these reviews reports that the use of masks by HCWs and non-HCWs can reduce the risk of respiratory virus infection by 80% compared to no-mask (OR = 0.20, 95% CI = 0.11–0.37). Furthermore, respirators were found to be more protective than surgical masks; and surgical masks more protective than cloth masks. There appears to be no difference between respirators and medical masks when used in non-aerosol generating procedures low-risk environments Conversely, no significant evidence was found that supported an equivalence claim of medical masks with respirators in their level of protection against COVID-19 or other similar viruses. In moderate and high-risk hospital settings, N95 are associated with more significant reductions in risk of contagion.

A systematic review based on experimental designs only found that N95 respirators halve the risk of any respiratory illness compared to surgical masks; the certainty of the evidence was low due to baseline differences, indirectness of evidence for COVID-19, and low event rates that account for imprecision. The reduction in contagion risk calculated from 2 RCTs was estimated to be: RR 0.43, 95% CI 0.29, 0.64; I² = 0%, from pooled analysis; with an absolute effect of preventing 73 (95% CI= 91 - 46) more infections per 1000 HCWs wearing N95 respirators compared with surgical masks.

Among the included studies, one reported on the use of Powered Air Purifier Respirators (PAPR). Based on observational studies, the authors report they did not found a difference in risk of contagion in HCWs when comparing PAPR devices with other, more compliant protective elements (N95, FFP2). They found that PAPR users reported higher heat tolerance but limited mobility and reduced audibility.

Regarding decontamination, we included a systematic review that assessed the effectiveness of ultra-violet germicidal irradiation (UVGI) for the decontamination of PPE and its impact on PPE performance. Their findings support that the use of a cumulative UV-C dose of at least 40,000 J/m² results in adequate decontamination without affecting performance or fit afterwards. Another review on the subject reported that mask (N95) performance was best conserved using dry heat decontamination, and that vaporous hydrogen peroxide, as well as UVGI, are effective decontaminants. However, its effect on surgical masks is unknown. The authors also state that bleach is not safe for decontamination since it alters mask performance and might be associated with health risk for users.
A systematic review that searched for barriers and facilitators of HCWs adherence to PPE protocols included 20 studies of moderate to high-quality overall (10 from Asia, four from Africa, four from Central and North America, and two from Australia). They report that HCWs were unsure to follow recommendations when they are long and ambiguous or do not reflect national or international guidelines. Some were overwhelmed because of constantly changing guidelines and by the increased workload and fatigue associated with PPE use due to preparation and cleaning. A serious concern was the lack of PPE or the low quality of the available items, pointing at a need to adjust supplies during the pandemic. HCWs reported that it was challenging to use masks and other equipment when it made patients feel isolated, frightened, or stigmatised. Of course, discomfort associated with wearing PPE was also reported.

**Discussion**

Our review aimed at summarising the available evidence of the effect of different PPE on the risk of COVID-19 infection among HCWs caring for patients requiring urgent trauma assessment and surgical care. We did not find experimental studies that assessed PPE on emergency trauma surgery settings during the pandemic. Limited observational evidence from COVID-19, indirect evidence from other healthcare settings, and other viral outbreaks were all considered to answer our research question given that the population (HCW) and intervention (PPE) of interest were the same and thus considered applicable to the emergency surgery setting.

The available evidence was consistent to show that the use of N95 respirators and surgical masks is associated with a reduced risk of coronaviruses respiratory illness compared with no mask use, with high certainty on this beneficial effect. In moderate to high-risk environments, especially in aerosol-generating procedures, evidence suggests that N95 respirators are associated with a more significant reduction in risk of COVID-19 infection compared with surgical masks; an effect seen in observational COVID-19 studies and experimental viral respiratory illness studies. Low-quality evidence estimates from these studies suggest a relative reduction of 50% in the risk of contagion associated with N95 respirators compared to surgical masks. Eye protection also significantly reduces the risk of contagion compared to no-eye protection. Furthermore, the decontamination of masks and respirators with ultraviolet germicidal irradiation, vaporous hydrogen peroxide, or dry heat is effective and does not affect PPE performance or fit. This evidence should inform decontamination and reuse protocols to avoid shortages and enhance resource allocation and use.

The costs associated with additional protective measures during the COVID-19 pandemic could be significant and affect healthcare institutions in low and middle-income countries. The cost-effectiveness of interventions must also be taken into consideration to generate recommendations during the current pandemic. The possibility to decontaminate and reuse different types of masks can be determinant in shortages and will probably reduce costs without affecting HCW’s safety. A cost analysis study compared the use of disposable FFP3 standard masks vs. SR
100 reusable respirators. Disposable masks are indicated to be replaced after each surgical case, and each one costs roughly $4.27 (USD). The cost per unit for a reusable respirator, supplied with an appropriate filter, is approximately $44(USD), and replacement filters cost $0.37. The authors of this economic evaluation highlighted that reusable PPE could be associated with considerable cost savings and estimated that the cost of acquiring a respirator is recovered after it is used for the care of 10 patients.

In a survey of 5,442 neurosurgical staff members in Hubei province, among 120 participants that were infected, 78.3% reported wearing surgical masks, and 20.8% failed to use any protection when exposed to the source of infection. A total of 1,287 operated under level 2 protection, and only one was infected, further illustrating the pertinence of wearing adequate PPE when caring for surgical trauma patients.

Expert recommendations developed from a study of emergency tracheal intubation in 202 patients with COVID-19 in Wuhan, China, notes that while PAPRs were the PPE of choice when face shields or full hoods without PAPR were substituted, there were no instances of infection of operators. As the risk of virus exposure due to self-contamination is high during the removal of PPE, educational training for proper donning and doffing of PPE as well as monitoring for compliance is essential. The minimum recommended PPE is eye protection, a fit-tested respirator (N95 or FFP3), a fluid-resistant gown, and gloves. The French guidelines recommend FFP2-type protective filtering masks when performing any aerosol-generating procedures. Guidelines for chest compressions recommend ‘level three’ PPE, which includes an FFP, disposable fluid-resistant gown, disposable apron, and gloves, fluid-resistant surgical mask, and eye or full-face protection. Recommendations for otolaryngologists include fluid-resistant FFP3/N95 mask, disposable and fluid resistant gloves, and gown, glasses, or a full face shield.

Recommendations for safe orthopaedic surgery practices state that surgery should only be performed on COVID-19 positive patients when the risks of surgery are outweighed by the benefits, such as in emergencies or when a surgical delay could cause increased morbidity and mortality. The recommended PPE are N95 respirators or PAPR with the use of face shields, isolation gowns, boot covers, and gloves.

Intubation of trauma patients is a high-risk-of-contagion procedure during the COVID-19 pandemic. A survey in 503 hospitals from 17 countries included 1,718 HCWs performing 5,148 tracheal intubations and measured a 10.7% incidence of COVID-19 infection after tracheal intubation. Most participants reported wearing gloves, gown, eye protection, and FFP2/FFP3/N95/N100 respirators. Simulation studies have assessed the effect of additional protective and preventive measures, such as transparent plastic boxes or PAPR, on the vision, comfort, and success of tracheal intubations.
A survey of HCWs realities and perceptions during the pandemic in Latin America included 936 participants and reported low access to disposable gowns (67.3%), N95 respirators (56.1%), and facial protective shields (32.6%). Even access to disposable surgical masks was reported by only 83.9% of participants. This emphasises the need for rational use of limited PPE during the pandemic in LMICs to ensure HCW safety without withholding urgent trauma care.

Our findings regarding decontamination should be considered as a feasible solution for the limited access to N95 equivalent respirators during shortages and in limited resources environments. Also, to avoid such shortages, it appears that N95 respirator equivalents use should be limited to moderate to high-risk environments; when caring for patients with confirmed COVID-19, or for suspicious or unknown status patients that need emergency surgery due to trauma.

**Strengths and Limitations**

Our review employed an automated search platform where evidence on COVID-19 is available. This strategy streamlined the rapid nature of the review while ensuring that all relevant studies were identified. Using an automated system has the additional long-term advantage of facilitating review updates by quickly identifying new studies that satisfy selection criteria. Our review also has the strength of having critically assessed all included studies. We report on the estimates and evidence grading of the identified high-quality systematic reviews. A metanalysis of systematic reviews results was not planned in our review protocol and was not considered adequate, given the overlap of included studies among reviews and the variation in selection criteria. Despite the differences between reviews, the consistency of findings among the reviews provides high certainty of the beneficial effects of PPE in the hospital setting. The main limitation of our review is that evidence from our specific setting of interest - emergency trauma surgery - was not identified. Nevertheless, extrapolation from other clinical settings such as the emergency room, COVID-19 wards and critical care during the pandemic was considered adequate given the characteristics of the intervention and the similarities to the setting of interest.

**Conclusions**

The use of PPE drastically reduces the risk of COVID-19 compared with no mask use in HCWs in the hospital setting. Respirators like N95 or equivalent provided more protection and were found to halve the risk of COVID-19 contagion in HCWs from moderate and high-risk settings. Eye protection also provides additional protection and is associated with reduced incidence of contagion. These effects apply to emergency trauma care. Decontamination and reuse appear as feasible, cost-effective measures than could help overcome PPE shortages and enhance the allocation of limited resources.
Recommendations for practice

When caring for a trauma patient with suspected or unknown COVID-19 status, HCWs should use at least N95 respirators or equivalents to reduce the risk of COVID-19 infection adequately. Decontamination with ultraviolet light, hydrogen peroxide, and dry heat should be made available.

Recommendations for research

Robust RCTs comparing the efficacy of surgical masks vs N95 respirators in HCWs caring for trauma patients are potentially unethical, as existing data show a significant protective effect, thus requiring emergency trauma surgery staff to wear N95 respirators when available. As of October 2020, there is a lack of consensus among international experts surrounding the topic of aerosol transmission, meaning that viral micro-droplets are capable of floating in the air without being pulled down by gravity. This means that if someone coughs, sings, or even breathes, the micro-droplets can stay in stagnant air for up to 16 hours, and with normal ventilation between 20 minutes to four hours. While multiple studies have discussed how SARS-CoV-2 can be found in aerosols, including one from May and another from April, a group of epidemiologists in late July characterised research on aerosol transmission as unconvincing and cited extensive published evidence from across the globe showing the overwhelming majority of viral spread is via large respiratory droplets. The CDC did not acknowledge aerosol transmission as an important route for viral transmission until September 2020, placing aerosol ahead of droplet transmission as the predominant mechanism of viral spread. However, just a few days later the statement was recalled, with updated guidelines saying HCWs need an N95 respirator for aerosol-generating procedures, only. The hospital administrators and epidemiologists who argue that the virus is mainly droplet-spread claim N95 respirators and strict patient isolation practices are not necessary for routine care of COVID-19 patients. It is essential to develop a complete understanding of the transmissibility of SARS-CoV-2 as it drives two different sets of protective practices, touching on everything from airflow within hospital wards to patient isolation to choices of PPE. Enhanced protections would be expensive and disruptive and would have strong implications on cost-effectiveness data, especially for low-income environments. Amid the uncertainty, adopting the highest possible forms of protection seems the best course of action.

To develop evidence-based recommendations to reduce the occupational risk of respiratory infection among medical personnel.

Protective effect of facemasks and respirators against respiratory infections among healthcare workers

Effectiveness of PPE in reducing the risk of clinical or laboratory-confirmed respiratory outcomes;

Healthcare settings amidst COVID-19 pandemic

P: HCWs; I: Any type of PPE; C: no PPE; O: Effectiveness of PPE in reducing the risk of clinical or laboratory-confirmed respiratory outcomes; 5 Healthcare settings worldwide. Study design: Published, peer-reviewed randomised control trials (RCTs) and observational studies;

6 RCTs and 23 observational studies

Cochrane RoB and RevMan for RCTs. Adapted Newcastle-Ottawa scales for case-control, cohort, and cross-sectional studies.

To evaluate the evidence behind UK Government PPE Guidance on surgical masks versus respirators for SARS-CoV-2 protection in patient-facing healthcare workers delivering secondary care.

UK guidelines comparing surgical facemasks and respirators specific to SARS-CoV-2

For laboratory studies, these data included study design, research question, masks/respirators tests, testing particle/pathogen, findings, and appraisal comments. For clinical studies, these data included setting, participants, interventions, outcomes, and limitations raised in appraisal.

Healthcare settings amidst COVID-19 pandemic

Any comparison between FRSM and respirator. Any study design containing primary data

9 studies

CASP Checklists

To examine the effectiveness of eye protection, face masks, or person distancing on interrupting or reducing the spread of respiratory viruses.

Social distancing, mask and hand hygiene either as stand-alone interventions or combined

 resolves any acute respiratory illness and its related consequences

Healthcare settings amidst COVID-19 pandemic

People of any age using face masks (i.e. surgical or medical masks and N95 respirators), eye protection, or person distancing against standard practice, or a similar physical barrier, or compared any of these interventions. Studies that reported a measure of acute respiratory illness – such as influenza-like illness, influenza, or respiratory infections – and/or its consequences (e.g. days off work, complications, hospitalisation and death, if clearly reported as consequences of the respiratory illness).

15 randomised trials investigating the effect of masks (14 trials) in healthcare workers and the general population and of quarantine (1 trial).

Cochrane RoB

To evaluate which type of full-body PPE and which method of donning or doffing PPE have the least risk of contamination or infection for HCW, and which training methods increase compliance with PPE protocols.

PPE with PAPR, more protective attire, not permeable not breathable (A), gowns versus aprons, one type of full-body PPE, sealed gown-glove interface, gown: easy to doff, gown with gown-glove improvement, gloves with tab, mask tabs, CDC method of doffing, single-step doffing, doffing with double gloves, donning and doffing with instructions, doffing with extra sanitation of gloves, doffing with hypochlorite, video-based learning

1) contamination of skin or clothing, measured with any type of test material to visualise contamination (e.g. stains made visible with UV light) or harmless viruses or bacteria; 2) infection with EVD, another viral haemorrhagic fever, or comparable highly infectious disease with serious consequences such as SARS, or COVID-19; 3) compliance with guidance on selection of type and use of PPE measured, for example, with an observation checklist 4) User-reported assessment of comfort and convenience 5) Costs or resource use 6) Time to don and doff the PPE.

Healthcare settings amidst COVID-19 pandemic

Controlled studies that evaluated the effect of full-body PPE used by HCW exposed to highly infectious diseases, on the risk of infection, contamination, or non-compliance with protocols. Studies that compared the effect of various ways of donning or doffing PPE, and the effects of training on the same outcomes.

24 studies with 2278 participants, of which 14 were randomised controlled trials (RCT), one was a quasi-RCT and nine had a non-randomised design. Eight studies compared types of PPE. Six studies evaluated adapted PPE. Eight studies compared donning and doffing processes and three studies evaluated types of training. Eighteen studies used simulated exposure with fluorescent markers or harmless microbes.

Cochrane RoB and ROBINS-I

- dry heat, autoclave, ethanol, isopropanol, bleach
- mask performance (filtration efficiency [FE] and airflow resistance); reduction in pathogen load; in vivo infection rates following use of treated masks; mask appearance or physical degradation; or adverse effects experienced by the wearer.

Healthcare settings amidst COVID-19 pandemic

P: HCWs donning surgical facemask PPE or their components
I: intervention(s) to decontaminate, sterilise or treat surgical masks (applied either before or after their use) for the purposes of reuse as PPE
C: no decontamination
O: a) mask performance (i.e. filtration efficiency and airflow resistance); b) reduction in pathogen load; c) in vivo infection rates following use of decontaminated masks; d) changes in physical appearance (i.e. mask appearance or physical degradation); e) adverse effects experienced by the wearer (e.g. skin irritation); or f) feasibility of the intervention (e.g. time, cost, resource utilisation). Prospective original research on decontamination interventions for surgical masks. Original research, including systematic reviews

Decontamination (n=1)
Pre-contamination (n=6)

Independent instrument evaluating RoB in study design, methodological consistency, population heterogeneity, sampling bias, outcome evaluation, and selective reporting

N95 respirators versus surgical masks.

- Primary outcomes: 1) SARS-CoV-2 infection; 2) Clinical respiratory illness (CRI).
- Secondary outcomes: (3) Influenza like illness (ILI); (4) Laboratory-confirmed respiratory viral infection; (5) Laboratory-confirmed bacterial colonisation; (6) Laboratory-confirmed respiratory infection; (7) Laboratory-confirmed influenza; (8) Discomfort of wearing respiratory protections.

Healthcare settings amidst COVID-19 pandemic

Randomised controlled trials (RCTs) run in healthcare settings. Randomisation was allowed both at individual and cluster level.

Four RCTs involving 8736 HCWs. No trial specifically on prevention of COVID-19

<td>Houghton C, Meskell P, Delaney H, Smalle M, Glenton C, Booth A, et al. 2020.</td>
<td>An information specialist (MS) designed and conducted all searches, which were informed by a topic expert and independently peer reviewed by an Information Specialist and Assistant Managing Editor at Cochrane. In order to ensure a range of respiratory infectious disease types were captured, all nine studies that looked at coronaviruses were included (MERS = 2 and SARS = 7), as, similarly to COVID-19, they have a mixture of contact, droplet, and airborne transmission. GRADE-CERQual (Confidence in the Evidence from Reviews of Qualitative research) approach to assess our confidence in each finding. Second, the data richness of the 27 remaining studies focusing on TB, H1N1 and general respiratory virus outbreaks was assessed. From these 27 studies, the studies that scored a 3 or higher for data richness were sampled.</td>
<td>Ireland</td>
<td>When new respiratory infectious diseases become widespread, such as during the COVID-19 pandemic, healthcare workers’ adherence to infection prevention and control (IPC) guidelines becomes even more important. Strategies in these guidelines include the use of personal protective equipment (PPE) such as masks, face shields, gloves and gowns; the separation of patients with respiratory infections from others; and stricter cleaning routines. These strategies can be difficult and time-consuming to adhere to in practice. Authorities and healthcare facilities therefore need to consider how best to support healthcare workers to implement them. Objectives: To identify barriers and facilitators to healthcare workers’ adherence to IPC guidelines for respiratory infectious diseases.</td>
<td>Views and experiences of nurses, doctors and other healthcare workers when dealing with severe acute respiratory syndrome (SARS), H1N1, MERS (Middle East respiratory syndrome), tuberculosis (TB), or seasonal influenza. Most of these healthcare workers worked in hospitals; others worked in primary and community care settings.</td>
<td>36 relevant studies and sampled 20 of these studies for analysis. Ten of these studies were from Asia, four from Africa, four from Central and North America and two from Australia. Studies that focused on the experiences and perceptions of healthcare workers with regards to IPC guidelines for respiratory infectious diseases were included. By definition healthcare workers meant any healthcare worker, including clinicians (e.g. doctors, nurses, midwives, clinical managers, allied health professionals, pharmacists) or other staff members (e.g. porters, healthcare assistants), with responsibility for patient care in any hospital, long-term care, primary care or community setting (adapted from...</td>

**Figure 1. GRADE summary of judgements**
**Description of studies**

- **Identification**: Number of records identified through a systematic search (N=258)
- **Screening**: Number of records after duplicates removed (N=258)
  - Number of records screened (title and abstract) (N=258)
  - Number of records excluded (N=134)
- **Eligibility**: Number of full-text articles assessed for eligibility (N=78)
  - Number of articles excluded on reading full-text (N=59)
    - Wrong study design (N=29)
    - Wrong intervention (N=23)
    - Wrong outcomes (N=1)
    - Wrong language (N=5)
    - Wrong patient population (N=2)
  - Number of articles assessed for quality (N=19)
  - Number of articles excluded on critical appraisal (N=0)
- **Included**: Number of articles included (N=19)

CONCLUSIONS

Recommendation

1. It is critical to ensure that at least the minimum requirements for the perioperative use of PPE are implemented as soon as possible for trauma cases requiring emergency surgery. Immediate implementation of wearing N95 respirators is likely to avoid no more than 51 infections per 1000 HCWs, in the worst-case scenario, making unethical the deferral of implementation until more studies are available.

- NIOSH-certified N95 respirator
- Eye protection (goggles or face shield)
- Cap and Gown
- Gloves (ideally double)
- Powered air-purifying respirator in aerosol-generating procedures, such as during induction of anesthesia and intubation, when available.

2. Proper technique while donning and doffing PPE is essential in avoiding unnecessary exposure to the virus. The best-designed and engineered items of PPE will fail healthcare workers and their patients if the PPE is donned or doffed incorrectly and contamination is spread.

3. Immersive simulation can be used to address the human, system, and technical elements of PPE. Simulation training ensures familiarity prior to patient care, providing a safe environment for the ‘deliberate practice’ of procedural skills, communication and teamwork, and management of medical emergencies.

4. It is suggested that a step-wise, standardized system of training be established to ease decision fatigue in already overworked HCWs. Building graphic illustrations and animated videos to aid in this educational process are essential.

- Inpatients who go to emergency surgery and who have clinical criteria for COVID-19 according to the guidelines of the Colombian Ministry of Health.
- Patients who require emergency surgery and who are symptomatic with known high-risk comorbidities for complications and COVID-19 mortality during hospitalization.
- Patients who are hospitalized or arrive directly to urgent procedures and have a confirmed history of being direct contacts of patients confirmed with COVID-19 or who have been in high-risk environments of contagion (hospitalization in ICU or emergency services) in the last 14 days.
