#### 13 Abstract :

14 Purpose: Determining the triggering factor of the sudden boost of the daily reported new COVID-19 15 cases arising in most European countries during 2020 Autumn.

16 Methods: The dates of the boost were determined using an automatic fitting of the two last months 17 reported daily new cases in 18 European countries of latitude ranging from 39° to 62°.

18 Results: The present study proves no correlation between the country boost date and its 2 weeks

19 preceding temperature, but shows an impressive linear correlation with its latitude. The country

20 boost date corresponds to the time when its sun UV daily dose drops below 30% of that of 0°

- 21 latitude.
- 22 Conclusions: Previous studies compared covid-19 severity between different populations. In
- 23 contrary, the date of the boost is an intrapopulation observation and can thus be only triggered by a
- 24 parameter globally affecting the population, i.e. the sun UV daily dose decreases. This result supports
- 25 low vitamin blood D level as a real primary cause of COVID-19 severity. Europe and US could thus
- 26 sink into a long crisis, since they will get back above the October sun UV dose only end 2021 March.
- 27
- 28

29 Keywords: covid-19, latitude, vitamin D, second wave

#### 30 Introduction

- 31 Most European countries underwent an unexpected spectacular boost of the daily new COVID-19
- 32 cases in autumn (Fig. 1), imposing in emergency new confinement rules

## 33

- 34 Figure 1: Examples of daily new COVID-19 cases (extracted from the Google home page when
- 35 searching "covid"). All curves exhibit a clear boost of the growing rates around October.
- 36
- 37 The most common reported explanation is the decreasing temperature. The aim of this data analysis
- 38 study is to challenge this assumption against a pure country latitude impact.
- 39

#### 40 Material and method

- 41 Data sources
- The daily reported country new COVID-19 cases were obtained by digitalizing the curves from the 42
- 43 Johns Hopkins coronavirus resource center (https://coronavirus.jhu.edu/map.html) using Digitizelt 44 (www.digitizelt.de).
- 45 The country population weighted center (PWC) latitudes were obtained from the Baylor University
- 46 population resource
- 47 (http://cs.ecs.baylor.edu/~hamerly/software/europe population weighted centers.txt)
- 48 The averaged 2 weeks temperatures preceding the boost dates were derived from weather.com.
- 49 The theoretical sun UV daily dose for vitamin D production, as a function of latitude and of the day of
- 50 the year was derived by interpolation from [1].
- 51
- 52 Boost date determination

medRxiv preprint doi: https://doi.org/10.1101/2020.10.28.20221176; this version posted November 8, 2020. The copyright holder for this preprint (which was not certified by peer review) is the author/funder, who has granted medRxiv a license to display the preprint in perpetuity. It is made available under a CC-BY-NC-ND 4.0 International license .

53 The date of the growing rate boost was automatically determined by fitting the two last months of

54 the daily new COVID-19 cases with:

55 
$$N_c e^{(\alpha_c + (\beta_c - \alpha_c) l(t - t_c)) t}$$
(1)

56 where l is the logistic function:

57 
$$l(t-t_c) = \frac{1}{1+e^{-\gamma(t-t_c)}}$$

- $t_c$  is considered as the boost date of the country c, i.e. the date when the exponential coefficient, 58
- coming from the initial value  $\alpha_c$ , crosses the value  $\frac{\alpha_c + \beta_c}{2}$  before tending towards  $\beta_c$  when  $t \to \infty$ .  $\gamma$ 59

(2)

- is the steepness of this changing.  $\gamma$  was assumed country independent as we search for an impact of 60
- the latitude of its own. This further allows to prevent an over-fitting of the data noise by a steepness 61
- 62 tuned for each country.
- 63 Note that as the exponential coefficient varies with time, the doubling time around the boost date is
- 64 not simply In(2) divided by this coefficient.
- 65
- **Results:** 66

Table 1 shows the fitting results (all the data and fitting process is provided in the supplementary xlsx 67

68 file).

87

- 88 Fig. 4 shows that the day of the second wave boost is well predicted by the moment when the sun
- 89 UV daily dose of the country becomes lower than 30% of that at latitude 0°.
- 90

- 91 Figure 4: observed day of the second wave covid-19 boost as a function of the day when the country
- sun UV daily dose drops lower than 30% of that at latitude 0°. Trendline forced to intercept (0,0).
- 93

# 94 Discussion:

- 95 Many studies support an impact of low vitamin D blood level on the respiratory impairment in
- 96 coronavirus or virus diseases [2], and also recently for the COVID-19 pandemic [3]. Low vitamin D
- 97 blood level is also more present in populations at risk: i.e. aged people [4], obese patients [5],
- 98 coloured skin people living in high latitude countries [6] and diabetic patients [7].
- However these studies compared the covid-19 severity between different populations. They cannot
  thus discriminate whether the vitamin D blood level is a primary cause of covid-19 severity or only a
- 101 consequence associated to another population weakness being the primary severity cause.
- 102 In contrary the date of the boost is an intrapopulation observation and can be only triggered by a
- 103 parameter globally affecting this population. As there is no temperature correlation but an
- 104 impressive latitude correlation (fig. 2), the remaining common parameter affecting these populations
- 105 at different times depending on the latitude is the sun UV daily dose.
- 106 The present study supports thus that lower vitamin D blood level is one of the primary cause of
- 107 increased COVID-19 severity. By increasing the coronavirus load in the respiratory track, the
- 108 contagiousness in the population is also increased explaining the wave boost.
- 109 The results are also in line with the low population mortality observed within ±35° latitudes [8], and
- also with the confinement success reported in Hubei which is located on the 31° latitude, regarding
- 111 that these regions are most of the year above the sun UV daily dose threshold (fig. 3: black dot-dash
- 112 line).

113

#### 114 **Conclusion:**

115 To the best of our knowledge, the present study is the first reported evidence that lower vitamin D 116 blood level is one of the primary causes of covid-19 severity.

117 Europe, and US as well, are starting this autumn a long covid-19 crisis as they will get back above the 118 October sun UV daily dose only end 2021 March.

- The bet to reduce the pandemic severity during the coming winter using controlled preventive 119
- 120 vitamin D supplementation could be considered [10].
