21

22   **BACKGROUND** Chronic Shoulder Pain (CSP) is a health problem that affects  
23   almost 67% of the general population. Almost a third of patients with acute shoulder pain  
24   syndrome don't respond to initial therapy with analgesics and need interventional therapy.  
25   Corticosteroid injection is the standard therapy. Prolotherapy has been demonstrated to be  
26   effective in other chronic pain syndromes, but not in CSP. The aim of this study was to  
27   determine the effectiveness of prolotherapy compared to local anesthetic injection in the  
28   treatment of chronic shoulder pain  
29  
30

31   **METHODS** Retrospective and comparative study of 77 patients from the National  
32   Institute of Oncology in Mexico City who received treatment for Chronic Shoulder Pain  
33   guided by ultrasound between 2017-2019. 57 patients were kept in the study for further  
34   analysis. 39 received infiltration with corticosteroids and 17 prolotherapy. Effectiveness of

35 therapies was determined based on the decrease in VAS score in next follow-up session.  
36 Statistical analysis were performed with SPSS and RStudio Software.  
37  
38

39       RESULTS□ 51% of patients with Chronic Shoulder Pain were unemployed.–84% of  
40 the patients needed 3 different types of analgesics before they received ultrasound guided  
41 local treatment. Prolotherapy was as efficient as local anesthetic injection, no matter basal  
42 pain severity or underlying shoulder diagnosis, despite prolotherapy being more used as  
43 treatment for Rotator Cuff Tendinopathy.

44       CONCLUSIONS□ Prolotherapy and corticosteroid injection guided by ultrasound  
45 have the same efficacy in pain relief for chronic shoulder pain in oncologic patients.  
46

56 **1.Introduction**

57       *Chronic Shoulder Pain (CSP) is a health problem that affects almost 67% of the*  
58       *general population with high economic and lifestyle burden<sup>1</sup>. Patients with an oncologic*  
59       *disease have an increased risk of developing shoulder pain after surgical interventions,*  
60       *radiotherapy, and the pathologic features of their underlying disease<sup>23</sup>. Even with*  
61       *pharmacologic treatment, almost a third part of patients with acute shoulder pain*  
62       *syndrome don't respond to initial therapy with acetaminophen, non-steroidal anti-*  
63       *inflammatory drugs (NSAIDs) or muscle relaxants and will develop chronic shoulder*  
64       *pain.<sup>4</sup> If initial therapy, such as NSAIDs, rest, and physical rehabilitation, fail to relieve*  
65       *pain and improve function, the second line of treatment may non-invasive treatment as*  
66       *local anesthetic injection or prolotherapy<sup>5</sup>.*

67       *Local corticosteroid (CS) infiltration is the second most common non-surgical*  
68       *therapy used to treat CSP, after the use of multiple analgesics. Almost 11% of patients*  
69       *with shoulder pain receive CS local infiltration in primary care<sup>6</sup>. There is uncertainty*  
70       *about CS injection efficacy as therapy of shoulder pain after recent evidence that*  
71       *demonstrate a small and transient pain relief without additional benefit to other therapies.*  
72       *Anesthetic infiltration and physical therapy show equal long-term results for function,*  
73       *range of motion and patient-perceived improvement<sup>78</sup>. Additionally, CS injections display*  
74       *multiple adverse effects, such as rotator cuff tendon degeneration, exacerbation of*  
75       *neuropathic pain and delay in tissue repair and tendon necrosis, possibly secondary to an*  
76       *increase of oxidative stress by an increase of glutamate receptor NMDARI that promote*  
77       *apoptosis after injection of CS<sup>9</sup>.*

78       *Prolotherapy (PT) is a non-surgical technique for the treatment of chronic painful*  
79       *musculoskeletal conditions. It's based in the infiltration of local tissues with irritating*  
80       *agents to promote fibrous repair in tissues like tendons, joints, or damaged ligaments<sup>10</sup>.*

The most common irritating agents used are hyaluronic acid, hypertonic dextrose, zinc, growth hormone, and autologous cells such as platelet-rich plasma<sup>11</sup>. PT has won field in recent years as treatment elected by patients, physicians and researchers. In figure 1 most common words used in PubMed publication about PT are represented. PT has demonstrated beneficial effects in function, pain relief, and quality of life in patients with osteoarthritis, plantar fasciitis and adhesive capsulitis; with high treatment adherence and patient satisfaction<sup>12 13</sup>. Bertrand et al. demonstrated prolotherapy efficacy vs placebo in Painful Rotator Cuff Tendinopathy treatment with pain improvement and a higher patient satisfaction.<sup>14</sup>

90 Figure 1.— Word Map of Prolotherapy research in PubMed

Figure 1 Word Map of Prolotherapy research in PubMed. The size of the words represent the frequency that this words have been used in PI research.

94

95           *An ultrasonography (US) approach has recently been added to the management of*  
96    *interventional shoulder pain. Therapy guided by ultrasonography (US) is an economic*  
97    *and fast tool to improve previously needle blinded procedures. It has the advantage of*  
98    *being less traumatic to tissues, because it allows puncture to the exact site of infiltration,*

99 *making this therapy more accurate<sup>1512</sup>. PT has not been studied previously in shoulder pain*  
100 *syndrome.*

101 *Both techniques have been widely used in pain control with local anesthetic*  
102 *infiltration, but the superiority for pain relief in these patients has not been compared. The*  
103 *aim of this study is to compare the efficacy of prolotherapy versus local anesthetic*  
104 *infiltration for pain relief guided by ultrasonography in patients with chronic shoulder*  
105 *pain.*

106

## 107 **2. Materials and methods**

### 108 **2.1 Study Design**

109 *Retrospective and comparative study of 77 patients recorded from the National*  
110 *Institute of Oncology in México City with diagnosis of CSP who received US guided*  
111 *interventional pain management between January 2017 and December 2019.*  
112 *Demographic data were collected from medical records and captured in a database.*

### 113 **2.2 Studied Population**

114 *Inclusion criteria were >18 years and CSP secondary to capsulitis, rotator cuff*  
115 *syndrome, or impingement syndrome. Exclusion criteria were incomplete medical records,*  
116 *patients with a primary tumor in the shoulder, combined technique, or history of*  
117 *previously infiltration. Other pathologies were excluded because low frequency (n=<2)*  
118 *with low statistical representation. The studied population was divided into patients who*  
119 *received nervous infiltration with local anesthetic, and those who were treated with*  
120 *prolotherapy. Mild efficacy of treatment was considered as relief of less than 30% of basal*  
121 *AVS score previous the intervention, moderate efficacy a reduction of 30-50% and, strong*  
122 *efficacy a decrease of >50% from basal AVS score. The present study has been carried*

123 *out under the Helsinki principles with number of approbation INCAN 2019/0140 by the  
124 local bioethics committee.*

125 **2.3 Statistical analysis**

126 *Statistical analysis was performed under IBM<sup>®</sup>, SPSS<sup>®</sup> software Version 25 ,  
127 WordMap was created in RStudio V 2.3.1 for MacOs Catalina Version 10.15.5 with  
128 Bibliometrix package<sup>16 17 18</sup>. Data distribution was calculated with Shapiro-Wilk test.  
129 Data is represented with median and standard deviations (SD). Median differences were  
130 determined by T student test; for categorical data X2 test and Fisher Exact Test were used  
131 as required. Statistical significance was considered with a p-value <0.05.*

132

133 **3. Results**

134 **3.1 Demographic patient characteristics.**

135 *77 patients received pain treatment guided by US between January 2017 and  
136 December 2019. 57 patients were selected according to inclusion and exclusion criteria.  
137 39 were assigned to the local anesthetic with corticosteroids group (CS) and 17 patients  
138 to the prolotherapy group (PT). Demographic features are represented in table 1. There  
139 were no differences in age, PT group was 60 ( $\pm 12.4$ ) vs 60 ( $\pm 14.06$ ) in LA ( $p>0.05$ ), 78%  
140 of PT patients were women vs 82% in LA but there was not statistical significance. 51% of  
141 the patients in both groups were unemployed when the first session of treatment was  
142 received. Prolotherapy treatment was more used when the left shoulder was affected. CS  
143 therapy was also used more when rotator cuff was affected (90% vs 83%,  $p<0.001$ ).  
144 Tumors in the stomach and kidneys were more frequent when prolotherapy was used. 84%  
145 of patients in both groups needed treatment with three different families of analgesics  
146 before US-guided pain treatment without differences between groups. There was no  
147 difference in basal severity of pain between the groups.*

148 **3.2 Effectiveness in pain control**

149 *Pain control was categorized as mild, moderate, or strong. First, we wanted to*  
150 *know if patient choice of the therapy was associated to basal pain severity, but we did not*  
151 *find any difference (fig 2). We then evaluated if pain control was dependent on the initial*  
152 *pain, table 2. PT demonstrated to be equal effective as CS to control pain, no matter the*  
153 *basal pain severity. Both groups had good results decreasing chronic pain in patients; 0%*  
154 *in both groups reported mild or no control of pain, 30% in CS had mild control vs 47% in*  
155 *PT group, and respectively 27% vs 56% reported strong control, without statistical*  
156 *difference between the groups ( $p=0.16$ ). (Fig 3).*

157 Figure 2.— Pain decrease by US guided procedure  
158

159  
160 *CS infiltration was more used in the treatment of rotator cuff syndrome (RCS) than*  
161 *prolotherapy. We evaluated if there is a difference in pain decrease based on the primary*  
162 *diagnosis of CSP. 35 patients in the CS group have RCS vs 15 in the PT group. PT group*  
163 *was equally effective as CS in pain control, with respectively 34% of patients with*

164 *moderate control vs 45%, and 66% vs 55% with strong relief of pain ( $p<0.21$ ). This*  
165 *control was not dependent of the number of different analgesics required after infiltration*  
166 *procedures, none of the groups needed 3 families of analgesics. 83% of CS group needed*  
167 *2 classes of analgesics, vs 57% PL. In the population with strong control, 56% and 50%*  
168 *required 2 classes of analgesics, respectively. None of the participants in this study*  
169 *presented adverse events.*

170 Figure 3.— Pain decrease based on initial severity.  
171

172

### 173 **3. Discussion**

174 *To our knowledge, this is the first study to evaluate the efficacy of CS vs PT for shoulder*  
175 *pain management. PT has demonstrated to be safe and effective in chronic pain therapy in*  
176 *many musculoskeletal pathologies, but just a few studies have investigated PT in CSP,*  
177 *even though it is the third most common musculoskeletal disorder in general practice<sup>6</sup>. As*

178 *in other studies reported previously, in this age group the main cause of CSP was Rotator  
179 Cuff Syndrome, with a frequency of 88% in the population of this study. This indicates that  
180 even though oncologic patients have an increased risk of CSP, the main cause is still  
181 Rotator Cuff Syndrome.<sup>15</sup> <sup>6</sup>There is no clear indication of prolotherapy for pain treatment  
182 in shoulder pathologies, but in this study, we have demonstrated that it is equally effective  
183 as CS injections for treatment of Capsulitis, Rotator Cuff Syndrome and adhesive  
184 capsulitis. Further studies are needed to evaluate each of the procedures separately in  
185 CSP.*

186 *Interestingly, almost 50% of patients in both groups were unemployed when they received  
187 local therapy. This agrees with other studies about the potential functional restriction that  
188 CSP leads to in patients, and the importance of a therapy that improves these functional  
189 restrictions. <sup>19</sup>Ultrasound guided pain management has been studied widely. This is a  
190 useful equipment for shoulder pain management <sup>15</sup>. Raeissadat et al. demonstrated in a  
191 prospective study that CS and PT in patients with plantar fasciitis has the same efficacy in  
192 pain relief after a 24-weeks follow up. <sup>12</sup> In this study, we have also demonstrated that the  
193 use of PT has the same efficacy as LA infiltration for chronic shoulder pain. We also  
194 found that pain relief does not depend on basal pain severity. The mechanism of PT  
195 effectiveness is based on the induction of anti-inflammatory reactions by irritant agents  
196 that enhance tissue healing. <sup>11</sup>*

197 *We are aware of the limitations of this study, as a retrospective study where we lack  
198 control of some variables of interest. However, to our knowledge this is the first study to  
199 evaluate the efficacy of PT vs CS for CSP. CS therapy requires multiples sessions, in this  
200 study PT and LA infiltration demonstrated to be safe when guided by US.*  
201 *CS and PT therapies have limitations in shoulder pain treatment. In randomized  
202 controlled trial, Kesikburun et al demonstrate that PT is not a therapy that should be used*

alone, its effectiveness is dependent of physical rehabilitation<sup>20</sup>. In this study, we have evaluated the use of PT and LA nervous infiltration separately. This study allows us to place PT as a safe technique when it is guided by US and enables future blinded studies in shoulder pain. PT is a promising technique, and it has demonstrated that its benefits are not limited to pain control, but also improvement of functionality and mobility.

208

209

210 **Conclusions**

211 *Most patients with CSP needs to receive pharmacologic treatment before receiving an*  
212 *interventional management. LA and PT have demonstrated to relieve pain in short term in*  
213 *these patients, regardless of the severity of basal pain. Prolotherapy is a safe and*  
214 *minimally invasive technique with high adhesion to treatment for pain control in CSP*  
215 *patients. It has the same effectiveness in pain relieve as CS nervous injection in oncologic*  
216 *patients, no matter the basal severity of pain. Further prospective, blinded and*  
217 *randomized studies with covariates as functional improvement are needed to prove PT*  
218 *long term benefits, but this study demonstrate that it is a promising treatment.*

219

220

## WHAT IS KNOWN

- 221 • *Patients with painful man syndrome need multiple therapies to have pain relief*  
222 • *Use of corticosteroid infiltration is therapy with few acute adverse events when*  
223 *performed by ultrasound.*

224 **WHAT IS NEW**

- 225 • *Prolotherapy is as effective as corticosteroid infiltration in pain relief of patients with*  
226 *painful shoulder syndrome.*  
227 • *When ultrasound guided prolotherapy is a safe therapy for handling painful shoulde*  
228 *syndrome.*

<b>Affected shoulder</b>				
Left	28(49%)	24(62%)	14(78%)	0.001*
Rigth	28(49%)	14(36%)	4(22%)	0.001*
Both	1(2%)	1(2%)	0(0%)	1
<b>Diagnosis</b>				
Capsulitis	3(5%)	3(8%)	0	0.54
Rotator cuff syndrome	50(88%)	35(90%)	15(83%)	<0.001*
Impingement syndrome	4(7%)	1(2%)	3(17%)	0.08
<b>Primary Tumor</b>				
Breast	29(51%)	22(56%)	8(44%)	0.26
Stomach	3(5%)	0(0%)	3(17%)	0.02*
Prostate	5(9%)	4(10%)	1(6%)	1
Kidney	3(5%)	0(0%)	3(17%)	0.02*
Other	17(30%)	13(33%)	4(22%)	0.53
<b>Basal Pain</b>				
Mild		5(13%)	2(12%)	0.64
Moderate		20(51%)	9(53%)	0.90
Severe		14(36%)	6(35%)	0.96
<b>Prior treatment</b>				
1 family	1(2%)	1(3%)	0	1
2 families	8(14%)	6(15%)	2(11%)	1
3 families	48(84%)	32(82%)	16(89%)	0.7

Data is represented in mean and SD for quantitative variable and absolute and relative frequencies for categoric data. Sd = Syndrome. Mean differences were calculated by U-Mann-Whitney test, for categorical data X2 and Fisher Exact test were used as required. \* Statistical significance when  $p<0.05$ .

TABLE II

DECREASE IN PAIN ACCORDING TO BASAL PAIN

BASAL PAIN	Treatment efficacy	CS (n=39)	Prolotherapy (n=18)	P value
MILD		<b>n= 5</b>	<b>n=2</b>	0.47
	Mild	0	0	
	Moderate	3(60%)	2(100%)	
	Strong	2(40%)	0	
MODERATE		<b>n=20</b>	<b>n=9</b>	
	Mild	0	0	0.53
	Moderate	8(40%)	3(33.3%)	
	Strong	12 (60%)	6 (66.6%)	
SEVERE		<b>n=14</b>	<b>n=6</b>	0.13
	Mild	0	0	
	Moderate	2(14%)	3(50%)	
	Strong	12(86%)	3(50%)	

MILD EFFICACY OF TREATMENT WAS CONSIDERED AS A RELIEF OF LESS THAN 30% OF BASAL THE VAS SCORE PREVIOUSLY THE INTERVENTION, MODERATE EFFICACY A REDUCTION OF 30-50% AND STRONG EFFICACY TO A DECREASE >50% FROM THE BASAL VAS SCORE. X<sup>2</sup> AND FISHER EXACT TEST WERE USED AS REQUIRED. \* STATISTICAL SIGNIFICANCE WHEN P<0.05.
