31 **Abstract**

32 SARS-CoV-2 seroprevalence in an antenatal population in Kingston, Jamaica was assessed for  
33 September-November 2020 in a repeated cross-sectional study using the Abbott Architect  
34 SARS-CoV-2 IgG assay. After adjusting for test performance, seroprevalence was 6.9% for  
35 September, 16.9% for October, and 24.0% for November. Of the 37 pregnant women testing  
36 SARS-CoV-2 IgG positive, only 3 were symptomatic. One symptomatic woman testing SARS-  
37 CoV-2 IgG positive had multiple co-morbidities and succumbed to COVID-19 pneumonia. Up to  
38 January 31, 2021, 8 women identified as SARS-CoV-2 IgG positive delivered, all without  
39 complications. Comparison of test adjusted seroprevalence data with cumulative PCR-confirmed  
40 COVID-19 cases within the Kingston Metropolitan Area indicated that as many as 44.4 times  
41 more people were infected with SARS-CoV-2 than identified with PCR testing. These findings  
42 provide the first evidence for the extent of SARS-CoV-2 infections in Jamaica and will inform  
43 future SARS-CoV-2 testing strategies.

44 The first confirmed COVID-19 cases in the Caribbean occurred in March 2020, with the first  
45 confirmed case of COVID-19 in Jamaica occurring on March 10, 2020.<sup>1</sup> Subsequent to the  
46 introduction of SARS-CoV-2 in Jamaica, governmental restrictions were imposed that included  
47 school closures (March 13, 2020), closure of international borders (March 21, 2020), and  
48 implementation of daily island-wide curfews (April 1, 2020). Restrictions were eased on June 1,  
49 2020 to reopen international borders, but up to January 2021 most schools have remained closed  
50 (virtual schooling) and island-wide curfews remain in effect. Up to August 2020, confirmed  
51 cases of COVID-19 in Jamaica remained below 1,000 and only 10 deaths were reported for the  
52 entire population of approximately 2.7 million people. Several weeks after the Emancipation Day  
53 (August 1, 2020) and Independence Day (August 6, 2020) holidays COVID-19 PCR-confirmed  
54 cases increased rapidly, followed by increased COVID-19 deaths, and on August 30, 2020 the  
55 Government of Jamaica declared COVID-19 community transmission. Up to January 31, 2021  
56 there have been 15,973 confirmed COVID-19 cases and 353 deaths in Jamaica.

57 Although it is clear that SARS-CoV-2 community transmission in Jamaica has led to a great  
58 increase in COVID-19 cases and deaths, it remains unknown as to the extent of transmission, as  
59 even in the most resourced countries most cases are not identified.<sup>2,3</sup> SARS-CoV-2  
60 seroprevalence studies can determine the extent of transmission within a population that can  
61 inform the public health response. This information can indicate whether the amount of testing is  
62 adequate and also informs transmission dynamics due to persons likely having some degree of  
63 immunity that have been infected recently.<sup>4</sup>

64 Samples collected from pregnant women seeking routine antenatal care are commonly used to  
65 provide prevalence estimates of disease, as is done in some sub-Saharan African countries to  
66 determine HIV prevalence.<sup>5</sup> More recently antenatal samples have been examined to provide a

67 prevalence estimate of SARS-CoV-2 infections.<sup>6</sup> Residual serum samples from pregnant women  
68 attending antenatal clinics provide a valuable tool to determine the extent of SARS-CoV-2  
69 infections in a population and are also a unique population due to possible risks of infectious  
70 disease not only to the pregnant woman but also to the fetus. Although SARS-CoV-2-infected  
71 pregnant women are commonly asymptomatic,<sup>7-9</sup> symptomatic pregnant women were recently  
72 shown to be at increased risk of severe disease.<sup>10</sup> Thus far, studies of COVID-19 in pregnancy  
73 show that poor outcomes are uncommon for both the mother and child, and vertical transmission  
74 appears to be rare.<sup>11</sup> COVID-19 studies in antenatal populations are limited, however, which has  
75 led several experts to promote increased COVID-19 surveillance and research of pregnant  
76 women.<sup>12</sup>

77 In this repeated cross-sectional study, we determined the presence of SARS-CoV-2 IgG in all  
78 University Hospital of the West Indies (UHWI) antenatal residual serum samples submitted  
79 during September-November 2020. The UHWI, located in Kingston, Jamaica, is the largest  
80 tertiary hospital in the country with approximately 1,600 deliveries each year. Most pregnant  
81 women attending the UHWI antenatal clinic reside in the Kingston Metropolitan Area, the most  
82 populous metropolitan area of Jamaica that is primarily within the parishes of Kingston and St  
83 Andrew. UHWI antenatal samples are routinely received in the Virology Laboratory of the  
84 University of the West Indies Department of Microbiology for HIV testing. A total of 249 unique  
85 patient samples (i.e., no patient was tested more than once) were tested for SARS-CoV-2 IgG.  
86 This study was approved by the UWI Mona Campus Research Ethics Committee (ECP 244  
87 20/21).

88 SARS-CoV-2 IgG testing was determined via the Abbott chemiluminescence immunoassay  
89 (CMIA) using an Architect *i*2000SR instrument. The Abbott Architect SARS-CoV-2 IgG assay

90 is CE marked and is EUA authorized by the FDA. Previous assessment of this assay in the adult  
91 Jamaican population did not include pregnant women in sensitivity analysis, but 20 samples from  
92 pregnant women were tested to determine specificity with one sample testing false positive (2.45  
93 S/CO).<sup>13</sup> An additional 32 antenatal samples collected in September-December 2019 (prior to  
94 SARS-CoV-2 introduction into Jamaica) were tested, with no samples testing SARS-CoV-2 IgG  
95 positive using the manufacturer's recommended cutoff of  $\geq 1.4$  S/CO (Figure 1A). Including the  
96 previous data with this data resulted in a specificity of 98.08% (95% CI: 89.74-99.95%) when  
97 using the manufacturer's recommended cutoff of  $\geq 1.4$  S/CO that maximizes specificity but  
98 underestimates true positives.<sup>14,15</sup> Lowering the cutoff value from  $\geq 1.4$  S/CO to  $\geq 0.4$  S/CO  
99 resulted in one additional false positive sample (0.64 S/CO) for a specificity of 96.15% (95% CI:  
100 86.79-99.53%). To determine the sensitivity of the Architect SARS-CoV-2 IgG assay for  
101 pregnant Jamaican women, we collected convalescent blood samples from SARS-CoV-2 PCR-  
102 confirmed pregnant women and tested sera for the presence of SARS-CoV-2 IgG (Figure 1B).  
103 Identification of SARS-CoV-2 PCR-confirmed pregnant women at the UHWI was challenging  
104 as most SARS-CoV-2 infected women were asymptomatic (see below). Of the 10 SARS-CoV-2  
105 PCR confirmed pregnant women recruited, 8 tested positive ( $\geq 0.4$  S/CO) for an overall  
106 sensitivity of 80% (95% CI: 44.39-97.48%).

107 Samples from all women attending the UHWI antenatal clinic from September-November  
108 2020 were tested, and 17 samples collected from the first week of March 2020 were also tested  
109 (Figure 2). The percentage of samples testing positive ( $\geq 0.4$  S/CO) for each month was: 0.0%  
110 (0/17) in March, 9.1% (7/77) in September, 16.7% (13/78) in October, and 22.1% (17/77) in  
111 November (Table 1). Of the 37 women testing positive ( $\geq 0.4$  S/CO), only 3 had a history of  
112 COVID-19 symptoms, consistent with previous observations that most pregnant women infected

113 with SARS-CoV-2 remain asymptomatic.<sup>7-9</sup> Only 8 of the 37 women testing positive ( $\geq 0.4$   
114 S/CO) had a SARS-CoV-2 PCR test up to the day of the sample collected that tested SARS-  
115 CoV-2 IgG positive, of which 3 were SARS-CoV-2 PCR positive. Of the 3 symptomatic women,  
116 2 were SARS-CoV-2 PCR-confirmed, with 1 woman requiring intubation and management in  
117 the intensive care unit that subsequently demised. Of note the deceased patient was obese, with a  
118 history of breast cancer, and was of advanced maternal age ( $>40$  years of age). Of the 8 mothers  
119 that delivered up to January 31, 2021, all neonates were born without complications with 2  
120 deliveries occurring at late pre-term gestations. The distribution of ages was similar between  
121 women testing SARS-CoV-2 IgG negative and SARS-CoV-2 IgG positive as determined by  
122 Pearson's Chi-squared test ( $p=0.164$ ). Antenatal samples received for the months of September-  
123 November for 2018-2020 were similar (Pearson's Chi-Square test;  $p=0.835$ ), indicating that  
124 COVID-19 was unlikely to affect prenatal visit attendance during September-November 2020.

125 For samples testing  $\geq 0.4$  S/CO, median monthly values showed a decreasing trend  
126 (Figure 2): 3.28 S/CO for September, 3.08 S/CO for October, and 2.08 S/CO for November (no  
127 samples in March tested  $\geq 0.4$  S/CO), indicating that seroreversion was likely occurring as has  
128 been reported previously for the Abbott Architect SARS-CoV-2 IgG assay.<sup>15-18</sup> Crude  
129 seroprevalences were adjusted for test performance alone and with adjustment for seroreversion  
130 as described in the supplementary methods (Table 1). Adjusting for test performance only  
131 resulted in SARS-CoV-2 prevalences of 6.9% in September, 16.9% in October, and 24.0% in  
132 November. Adjusting for both test performance and seroreversion showed SARS-CoV-2  
133 prevalences of 6.9% in September, 18.2% in October, and 28.5% in November.

134 Our data identifies an underappreciated prevalence of SARS-CoV-2 infections among  
135 antenatal women in the Kingston Metropolitan Area and provides an approximation of the extent

136 of infections within the area. There were 2442, 3204, and 3590 cumulative confirmed COVID-19  
137 cases in the parishes of Kingston and St Andrew in September, October, and November,  
138 respectively (Ministry of Health and Wellness). Thus, of the 669,773 persons inhabiting the  
139 parishes of Kingston and St Andrew (Statistical Institute of Jamaica, 2018), the percentage of the  
140 population identified to be infected with SARS-CoV-2 via PCR and serology (with test  
141 adjustment only), respectively, was 0.36% and 6.9% in September, 0.48% and 16.9% in October,  
142 0.54% and 24.0% in November. This data indicates a 19.2-44.4-fold difference between  
143 serological identification of persons infected compared to SARS-CoV-2 PCR-confirmed cases,  
144 which is likely a slight underestimate due to seroreversion. The large disparity between SARS-  
145 CoV-2 PCR confirmed cases and those identified by antibody in this study highlights the  
146 difficulty of identifying SARS-CoV-2 cases with PCR testing, particularly in a resource-limited  
147 setting, and the utility of SARS-CoV-2 antibody testing to approximate population exposure.

148 Although our study provides the first assessment of the extent of SARS-CoV-2 infections in  
149 Jamaica, SARS-CoV-2 has not spread throughout the island uniformly, limiting our ability to  
150 draw conclusions about the extent of virus infections throughout Jamaica. Future studies  
151 examining additional populations in Jamaica will be informative to identify the extent of SARS-  
152 CoV-2 circulation across the island.
