## **Abstract**

We propose a prognostic dynamic risk stratification for 48-hour in-hospital mortality in patients with COVID-19, using demographics and routinely-collected observations and laboratory tests: age, Clinical Frailty Scale score, heart rate, respiratory rate, SpO<sub>2</sub>/FiO<sub>2</sub> ratio, white cell count, acidosis (pH < 7.35) and Interleukin-6. We train and validate the model using data from a UK teaching hospital, adopting a landmarking approach that accounts for competing risks and informative missingness. Internal validation of the model on the first wave of patients presenting between March 1 and September 12, 2020 achieves an AUROC of 0.90 (95% CI 0.87–0.93). Temporal validation on patients presenting between September 13, 2020 and January 1, 2021 gives an AUROC of 0.91 (95% CI 0.88-0.95). The resulting mortality stratification tool has the potential to provide physicians with an assessment of a patient's evolving prognosis throughout the course of active hospital treatment.

## **Introduction**

SARS-CoV-2 virus infection, the cause of COVID-19, results in a spectrum of disease ranging from asymptomatic infection through to life threatening disease requiring critical care, and even death. For patients admitted to hospital, it is essential to identify who is at risk of deterioration and death to enable timely targeted interventions (such as immune modulation and mechanical ventilation), to facilitate appropriate resource allocation and patient flow, and to inform discussions with patients and families.

Most existing disease severity prediction models for COVID-19 use only data that are available at the time of admission to hospital. Numerous such models have been proposed for both mortality and composite escalation/mortality outcomes, including new and re-purposed severity and early warning scores [1–7] and time-to-event models [8–13]. Most, however, perform only moderately well and are at high risk of bias [14].

While some markers of severity, such as sex and age can be assumed constant for the duration of the hospital visit, others, such as clinical observations and blood test results, can change markedly over the course of admission. COVID-19 is a dynamic disease in which patients can deteriorate over a short time period or suffer acute complications e.g. thromboembolism [15–16]. This may have a significant effect on a patient's prognosis that cannot be foreseen by a point-of-admission model.

Dynamic models that assimilate clinical data as it accrues may provide more accurate and clinically useful prediction of a patient's clinical course and prognosis over the subsequent days than that of point-of-admission models. Predictive models that incorporate post-admission information are limited in number and scope. Some models using information from the first four or five days after admission to predict mortality or deterioration have been proposed, but do not continue beyond the first few days of admission [17–18]. Other more recent models have made use of additional post-admission data, using a time-varying Cox model for mortality and escalation [19] or a machine learning model for mortality [20]. While indicating promising discrimination, these models use clinically unjustifiable or unclear methods for handling missing data and censoring, and do not account for informative missingness or consider the effect of treatments. Informative missingness describes the fact that in routinely-collected data the availability (or absence) of a result or observation may be related to the probability of the outcome. For example, a more extensive panel of investigations may be sent in patients thought

more likely to benefit from Intensive Care Unit (ICU) admission. While often ignored, such effects can be strong in Electronic Health Record (EHR) data [21–22].

We propose a prognostic risk stratification score for hospital patients with COVID-19, based on prediction of mortality in the subsequent 48 hours, using routinely-collected clinical data. The model is based upon a principled statistical approach called landmarking [23] that allows inclusion of any time-varying clinical parameters recorded prior to the time of prediction, whilst appropriately accounting for censoring and changes in the set of patients at risk. Our model further accounts for informative missingness and competing risks, which arise when there are two or more mutually exclusive outcomes: for example, once a patient is discharged, the risk of in-hospital mortality (during that admission) is removed, and therefore discharge is a "competing risk".

## **Methods**

### **Study design**

This is a retrospective cohort study of all patients presenting to Cambridge University Hospitals, a regional, tertiary care, university hospital in the East of England, between March 1, 2020 and January 1, 2021. This hospital is the sole admission hospital for patients in its immediate catchment population with COVID-19, and is a regional referral centre for a wide range of specialist services (not including ECMO).

The model was trained using data from patients presenting between March 1, 2020 and September 12, 2020 (hereafter "Wave 1"). A temporal validation of the model was then performed using patients presenting between September 13, 2020 and January 1, 2021 (hereafter "Wave 2").

We report our findings according to the Transparent Reporting of multivariate prediction models for Individual Prediction Or Diagnosis (TRIPOD) reporting guidelines [24].

### **Study Population**

All adults ( $\geq 18$  years of age) presenting to hospital during the study period and diagnosed with COVID-19 were included. Diagnosis was based on either a positive diagnostic SARS-CoV-2 test during or up to 14 days prior to the hospital visit, or a clinical diagnosis of COVID-19.

Diagnostic testing used either a real-time reverse transcription polymerase chain reaction (RT-PCR) of the RdRp gene from a nasopharyngeal swab, or the SAMBA II point-of-care test used at the hospital [25]. Patients with clinically diagnosed COVID-19 (based on symptoms, and in the opinion of the treating clinician) were included because diagnostic testing was limited during the early stages of the pandemic [26]. Clinical diagnosis of COVID-19 was identified using International Classification of Diseases 10th Edition (ICD-10) codes in the EHR.

We include only the first hospital visit for each patient after the positive test; any re-admissions were excluded. Nosocomial infection was defined as a first positive SARS-CoV-2 test or diagnosis more than 10 days after hospital admission. Since the first prediction by our model is made at 6 hours (to allow time for laboratory investigations), patients who died, were discharged or were classified as end of life within 6 hours of presentation to hospital were excluded.

All patients were treated as per standard treatment approaches, as guided by detailed local guidance in use in the hospital at the time. Patients were also eligible for inclusion in relevant clinical trials running at the hospital during the study period. These studies were the TACTIC-E and TACTIC-R trials (ISRCTN11188345 <https://doi.org/10.1186/ISRCTN11188345>), the REMAP-CAP platform trial for intensive care patients (ISRCTN67000769 <https://doi.org/10.1186/ISRCTN67000769>), and the RECOVERY trial (ISRCTN50189673 <https://doi.org/10.1186/ISRCTN50189673>).

## **Outcomes**

Throughout each patient's hospital visit, we aim to predict all-cause in-hospital mortality during the next 48 hours, a time period that we refer to as the "prediction horizon". We also consider two other outcomes, which are competing risks for the primary outcome: transfer to a tertiary Intensive Care Unit (ICU) for ECMO; and discharge from the hospital due to clinical improvement. Patients were followed up until January 3, 2021.

## **Ethics**

The study was approved by a UK Health Research Authority ethics committee (20/WM/0125). Patient consent was waived because the de-identified data presented here were collected during routine clinical practice; there was no requirement for informed consent.

## **Data collection**

The study used routinely collected data, extracted in anonymised form from the hospital EHR system, Epic (Epic Systems Corporation, Verona, Wisconsin).

We selected a list of 59 candidate clinical parameters (Table S1) that have been included in existing point-of-admission prediction models or were clinically judged to be likely predictors. These are divided into five categories: demographics; comorbidities; observations; laboratory tests; and treatments, interventions and level of care.

## **Demographics**

Basic patient demographics were extracted from the hospital EHR: age, sex, ethnicity, and Body Mass Index (BMI).

## **Comorbidities**

Twelve comorbidities that have previously been associated with COVID-19 [27] were identified by the presence of the corresponding ICD-10 codes entered in the EHR prior to the time at which the prediction is made (either before or during the hospital visit). Table S2 provides the ICD-10 codes used to define each comorbidity. In addition to specific comorbidities, frailty amongst patients over 65 years old was assessed by the Clinical Frailty Scale (CFS) score [28]. For patients for whom a CFS score had not been recorded by the treating team, a consultant or specialist registrar in Geriatric Medicine reviewed the clinical records and assigned a CFS score using only information recorded at the time of admission [29]. This approach has been shown to have good agreement with CFS scores assigned after face to face assessment (inter-rater reliability kappa 0.84) [30].

## **Observations**

We included the following observations that are regularly recorded in the EHR: heart rate (HR), mean arterial pressure, temperature and respiratory rate (RR). We summarised the measurements recorded over the previous 24-hour period as follows: mean, minimum and maximum value. We also calculated the trend as the difference between the median value for the last 24 hours, and the median value for the 24 hours prior to this. The Glasgow Coma Score (GCS) was extracted from the EHR; patients without a recorded GCS were assumed to have a GCS  $\geq 12$ . PaO<sub>2</sub>/FiO<sub>2</sub> (P/F) and SpO<sub>2</sub>/FiO<sub>2</sub> (S/F) ratios were calculated to indicate the

severity of hypoxia [31–32]. SpO<sub>2</sub> itself was not included as a potential predictor as our exploratory work suggested that, without accounting for FiO<sub>2</sub>, this largely reflected a patient's assigned oxygen saturation targets, and therefore acted as a proxy for underlying respiratory disease. Where only oxygen flow rate was available, FiO<sub>2</sub> was estimated according to the EPIC II conversion tables [33].

### **Laboratory tests**

For each of the 31 laboratory tests we considered, we included results up to 48 hours prior to the time at which the prediction was made. Where more than one result was available, we used the most recent result. In addition, for 7 of the most frequently measured blood tests (C-reactive protein (CRP), white cell count (WCC), platelets, haemoglobin, creatinine, sodium, potassium), we included the trend, defined as the difference between the median value for the last 24 hours, and the median value for the 24 hours prior to that. The neutrophil/lymphocyte and Interleukin-6/Interleukin-10 (serum IL-6/IL-10) ratios have previously been identified as prognostic, therefore we also considered these as potential predictors [9, 18, 34]. For blood markers where both abnormally low and abnormally high results could potentially be associated with poor prognosis (sodium and blood gas pH), we included the maximum deviation below and above the standard range in the previous 24 hours. We adjusted venous pH results by adding 0.03 to approximate arterial pH results [35].

### **Treatments, interventions and level of care**

We included 5 indicators of treatments, interventions and levels of care. The level of care of the patient was summarised by whether the patient had been in an ICU bed in the previous 24 hours. Mechanical ventilation was defined as patients receiving invasive ventilation during the previous 24 hours, either via endotracheal tube or tracheostomy. The use of renal replacement therapy during the last 24 hours was identified from the EHR. Cardiovascular support was defined as the administration of any vasopressors or inotropes in the last 24 hours. We also included in-hospital steroid administration prior to the prediction time, given that steroids can decrease the risk of death in patients with COVID-19 and that clinical trials operated in our hospital for part of the study time [36-37].

### **Model development**

We use the landmarking approach to dynamic prediction [23, 38-39]. Landmarking fits a series of models at a sequence of fixed time origins called landmark times. These are the time points at which we extract the data used to develop the proposed model. At each landmark time, a time-to-event model is used to describe the likelihood of the event occurring within the next 48 hours (the “prediction horizon”). Only data recorded before (or at) the landmark time are used in each model; no data from the future can be used. If the event of interest happens after the prediction horizon then the event is treated as censored at this landmark. Patients who have had any event prior to the landmark time are excluded, since these patients are no longer at risk. We use the supermodel approach in which the time-to-event model is assumed constant across landmark times [40].

Our landmark times are every 24 hours during the hospital visit, starting 6 hours after presentation to the hospital, to allow sufficient clinical information to accrue for prediction at the initial landmark to be feasible. We only use data at each landmark time from patients being actively treated for COVID-19 at that point in time. Landmark times after a patient transitions to end of life care were excluded, meaning that once patients transition to end-of-life care no further predictions are made, but any events occurring within the existing prediction horizon are still included (i.e. transitions to end-of-life care are not treated as censoring events). For patients with nosocomial infection only landmark times subsequent to the diagnosis of COVID-19 are included.

We use a Fine-Gray competing risk model [41–42] to account for the competing risks of in-hospital death, which are transferral for ECMO and hospital discharge.

We handle missing data using the missingness indicator approach because the recording in the EHR of a clinical parameter, regardless of the value, is often indicative of the treating health professional’s contemporaneous view of the patient’s prognosis [43–44]. To do this we augment the set of potential predictors with binary variables that indicate whether, during the window of time we consider, any measurement of the corresponding parameter is available for that patient. The missing indicator approach avoids the need to make the missing at random (MAR) assumption that is unlikely to hold in these data [45].

To select the most predictive parameters into the model we used standard penalised variable selection, specifically Smoothly Clipped Absolute Deviations (SCAD), with the tuning parameter

chosen to minimise the Bayesian Information Criterion [46]. We paired parameters together with their corresponding missingness indicator to prevent inclusion of an incompletely-observed parameter without its missingness indicator, using the group SCAD [47]. We also allowed missingness indicators to be included by themselves, in case the presence of a parameter is informative irrespective of its value.

All analyses were conducted in R version 3.6 [48].

### **Model assessment**

The discriminative ability of our model was assessed visually using the Receiver Operator Characteristic (ROC) curve, showing the false positive rate (FPR, also equal to 1-specificity) against true positive rate (TPR, also equal to sensitivity); and the Precision-Recall (PR) curve, showing precision (positive predictive value, PPV) against recall (sensitivity). PPV is the key metric for a dynamic predictive model such as we propose, because the low incidence of the primary outcome leads to a strong imbalance of events and non-events that is not accounted for by the ROC curve [49]. We also assess the Number Needed to Evaluate (NNE), defined as the number of patients needed to evaluate in order to identify one in-hospital death within the prediction horizon, calculated as  $1/PPV$ .

Quantitative assessment of discrimination was performed using the Area Under the ROC (AUROC) curve, in which 0.5 indicates no discrimination and 1.0 indicates perfect discrimination. For validation of the performance of the model on the training data, in addition to the unadjusted AUROC, we also performed repeated 5-fold cross-validation to account for uncertainty and over-optimism due to the complete model building process (including variable selection) [50]. We also calculate the Area Under the PR Curve (AUPRC) since it provides a clearer performance summary than AUROC when the primary outcome has low incidence, as here [51].

We assessed calibration visually using a calibration plot of predicted risk against observed mortality rate. We also quantitatively assessed the calibration slope, testing whether  $\beta=1$  in the logistic regression model  $\text{logit}(\text{probability of death}) = \alpha + \beta * \text{logit}(p)$ , where  $p$  is the risk score; and calibration-in-the-large, testing whether intercept  $\alpha=0$  when fixing  $\beta=1$  [52].

## **Results**

### **Baseline characteristics and outcomes**

519 patients presented to hospital with COVID-19 during Wave 1 (March 1, 2020 and September 12, 2020), of whom 46 were excluded due to discharge (34), death (2) or transition to end of life care (10) prior to the first landmark time (i.e. within 6 hours of presentation). 473 patients were therefore included in the development of the model.

Table 1 shows baseline characteristics, comorbidities and severity markers of all patients. The median age was 69 years. 196 (41.4%) patients were female. 99 patients (20.9%) died during their hospital admission, 5 patients (1.1%) were transferred for extracorporeal membrane oxygenation (ECMO) and 369 (78.0%) were discharged from hospital alive. The median length of hospital stay was 10.8 days. 103 patients (21.8%) were admitted to ICU of whom 82 required mechanical ventilation, 86 required cardiovascular support and 32 required renal replacement therapy. 36 (7.6%) patients had nosocomial infection and compared to the rest of the cohort were slightly younger (median age 65) and more likely to be male (66.6%) but had a similar mortality rate (22.2%).

### **Development of prediction model**

In total we include 6846 landmark times for training the model, with a median of 9 (IQR 3–17) landmark times per patient. In the 48-hour prediction horizon following these landmark times, there were 119 in-hospital death events (1.7% of landmarks), 658 hospital discharge events (9.6%) and 10 transfers for ECMO (0.1%). Note that, since landmarks occur every 24 hour and the prediction horizon is 48 hours, patient events will usually occur within the prediction horizon of two adjacent landmark times. Table S1 reports summary statistics, missingness and the number of measurements available per landmark time for each predictor. No patients were excluded due to missing data.

### **Model results**

Our proposed model for 48-hour in-hospital mortality includes age, Clinical Frailty Scale (CFS) score, heart rate (HR), respiratory rate (RR), oxygen saturation/fraction of inspired oxygen (SpO<sub>2</sub>/FiO<sub>2</sub>) ratio, white cell count (WCC), acidosis (pH < 7.35) and Interleukin-6 (IL-6). The

estimated coefficients are shown in Table 2, and the estimated hourly baseline cumulative subdistribution hazards are in Table S3.

### **Internal performance assessment**

Figure 1 shows the internal performance metrics. The unadjusted internal area under receiver-operating characteristic curve (AUROC) was 0.90 (95% CI 0.87–0.93) and the median cross-validation AUROC was 0.87, both indicating good discrimination (Figure 1A). The precision-recall (PR) curve (Figure 1B) also shows good discrimination, with an area under precision-recall curve (AUPRC) 0.31, in a population with 48 hour in-hospital mortality of 0.017 (1.7%), and the number needed to evaluate (NNE) < 10 for sensitivity less than 0.75 (Figure 1C). Figure 1D shows the calibration plot. The calibration intercept  $\alpha = -0.02$  (95% CI -0.22–0.17) indicates that the mean predicted probabilities match the mean observed mortality, while the calibration slope  $\beta = 1.16$  (95% CI 1.02–1.31) suggests that the observed mortality in high predicted risk patients slightly exceeds the predicted mortality risk.

### **Temporal validation of prediction model**

We assessed the performance of the model by applying it to held-out data corresponding to visits during Wave 2 (September 13, 2020 and January 1, 2021). 405 patients presented to the study hospital during this period. In total we include 3086 landmark times for training the model, with a median of 4 (IQR 1–10) landmark times per patient. In the 48-hour prediction horizon following these landmark times, there were 55 in-hospital death events (1.8% of landmarks), 441 hospital discharge events (14.3%) and 0 transfers for ECMO (0%). Characteristics are summarised in Table 1. Of note, compared to Wave 1, patients presenting in Wave 2 were younger (median age 61 vs 69) and more likely to be female (50.1% vs 41.4%). Note that because follow-up continued until January 3, 2021, the outcome during the 48-hour prediction horizon was known for all landmark times up to January 1, 2021, and so patients remaining in hospital at the study end-date could be included in the validation.

Figure 2 shows the temporal validation performance metrics, obtained by applying the trained model to the Wave 2 patients. The receiver-operating characteristic (ROC) curve (Figure 2A) shows the model continues to discriminate well, with AUROC 0.91 (95% CI 0.88–0.95). The PR curve (Figure 2B) shows that the positive-predictive value (PPV) is consistently well above the 48-hour in-hospital mortality incidence of 0.018 (1.8%) in the Wave 2 cohort across all

sensitivities, with AUPRC 0.21, and NNE  $< 10$  for sensitivities between 0.01 and 0.87 (Figure 2C). Figure 2D shows the calibration plot, which shows a tendency of the model to underpredict risk in the higher risk patients: calibration-in-the-large was 0.33 (95% CI 0.04-0.60), suggesting the mean of the predicted probabilities is lower than the mean observed mortality, and calibration slope 1.15 (95% CI 0.95-1.37), indicating that the spread of predicted risk corresponds reasonably well with the spread of observed mortality.

## **Discussion**

SARS-CoV-2 causes a wide spectrum of disease, from mild and short lived disease, through to more severe disease that can evolve over weeks, and may necessitate critical care management and even result in death. There is a pressing clinical need to be able to anticipate both disease severity and the trajectory of illness in order to facilitate patient management, resource allocation, and inform discussions with both patients and families.

Although risk factors for severe disease, such as age and male sex have been widely recognised, these static risk factors provide little nuance or discrimination at the individual patient level. Disease severity models have been proposed that provide a more accurate assessment but these have focused on a single time point such as admission to hospital, and do not respond to changes in the clinical picture as the disease evolves. The model described herein uniquely incorporates both static risk factors (age and CFS) and evolving clinical and laboratory data, providing a dynamic 48-hour risk prediction model that can adapt to both sudden and gradual changes in an individual patient's clinical condition. Our model is further strengthened by the competing-risk landmarking approach we adopt, allowing the model to account for events other than death that remove the patient from the population at risk.

The data used in the model were routinely collected demographic and clinical data from during the patient's hospitalisation, and were automatically extracted from patient EHRs. As such, this model could be readily incorporated into routine clinical care, providing invaluable information to clinicians on the ground who are managing patients with COVID-19. More broadly, our model highlights the potential utility of EHR data to inform our understanding of disease by making it feasible to collect and analyse the detailed data accrued during routine care, in contrast to the limited information that can be gathered via manual data collection.

Several methodological aspects of our approach further strengthened our model. Firstly, we account for competing risks in the model. Competing risks refers to the situation whereby the outcome (risk) of interest (in this case in-hospital mortality) can only happen whilst the patient is in hospital, and therefore the outcome of interest is ‘competing’ against the risk of transfer to another hospital and/or discharge from hospital. Allowance for this has been shown to be important in predictive modeling [53]. Secondly, allowance was made for the potential of the availability of observations and investigations to in itself be a reflection of disease severity. For example, the fact that an arterial blood gas has been taken may reflect the clinical impression that a patient is deteriorating. While multiple imputation is often used in clinical prediction models because it gives unbiased estimates under the missing at random (MAR) assumption, it is unlikely that the MAR assumption holds in the routinely-collected EHR data that we use [45]. The missing indicator method that we adopt does not rely on the MAR assumption and has been found to lead to improved predictive performance in EHR data [43-45]. Furthermore, we do not seek to make prognostic predictions for patients after clinicians have identified them as entering the last few hours or days of life. Such patients are commonly transitioned to a symptom management approach, in which observations, investigations and active treatment are discontinued: in our data, no vital sign observations were recorded on 43% of days during end-of-life care, compared to 0% of days during active treatment. This extreme missingness is therefore a strong predictor of mortality, and including these end-of-life time periods would distort the model for other patients by exaggerating the importance of missing data. In addition, predicting end-of-life after it is clinically apparent would have little clinical utility.

Several predictors of disease severity selected by our model have also been identified by models that aimed to assess severity of disease at the point of admission to hospital, and in epidemiological studies of risk factors for severe disease. Increasing age is widely recognised as being the strongest predictor of poor outcome from COVID-19 [3, 11, 27]. Frailty has similarly been shown to be a strong independent predictor of mortality in hospitalised older adults [54], including those with COVID-19 [29,55], and it is therefore unsurprising that the frailty score was selected in the model.

The deleterious effect of SARS-CoV-2 infection on respiratory function is one of the commonest and often most severe effects of illness, and frequently precipitates hospital admission and the need for critical care. Markers of respiratory function, including respiratory rate [3, 4, 12] and SpO<sub>2</sub>/FiO<sub>2</sub> (S/F) ratio [56] have been included in previous point-of-admission models; similarly

the recent ISARIC 4C deterioration model includes SpO<sub>2</sub> and the need for supplemental oxygen [3]. The S/F ratio, as selected by our model may be a more informative measure of respiratory compromise as it allows a fully quantitative rather than dichotomous measure of the need for additional oxygen, as well as allowing for the confounding effect of variation in the target oxygen saturations in different patient groups. Clinicians often set a lower target SpO<sub>2</sub> in patients with pre-existing respiratory disease, and thus oxygen therapy is not initiated until a much lower SpO<sub>2</sub> is reached compared to otherwise healthy patients.

Our model selected two markers of infection and inflammation: WCC and IL-6. This is consistent with other findings [11, 57–58]. IL-6 was included in the routine COVID-19 panel of blood tests at the study hospital but we recognise that this may be less commonly requested in other hospitals. To assess whether C-reactive protein (CRP) could serve as a proxy for IL-6 in our model when it is not available, we refitted the model with CRP in place of IL-6 (Tables S4–S5). The AUROC is slightly lower on both training (0.89, 95% CI 0.85–0.93) and test (0.83, 95% CI 0.78–0.89) data, yielding a slightly weaker but potentially more broadly applicable model. The preference of the model for IL-6 over CRP may reflect the fact that IL-6 is responsible for the production of CRP and, as such, is an earlier and more dynamic marker of the inflammatory response [59].

The inclusion of acidosis in our model is more novel, although it has previously been noted as a marker of disease severity [60]. Acidosis frequently complicates respiratory, renal and advanced circulatory failure in patients, and is therefore frequently observed in patients with severe disease. The separate inclusion of the severity of acidosis and alkalosis in our set of candidate predictors removed the need to assume a linear effect of pH, allowing pH changes in either direction to be accounted for. This would avoid, for example, a minor negative effect of alkalosis from masking a more major effect of acidosis.

There are several limitations to our study. We have not incorporated imaging data that have been used as a proxy for disease severity in some clinical trials, although we have included an extensive set of relevant clinical information. We also chose to include only laboratory results up to 48 hours and vital signs up to 24 hours before the landmark time. Exploiting older data in addition might improve the predictive ability of our model, but would also be likely to increase the model's complexity considerably, and therefore decrease its real-world utility. Our data were gathered from a single centre, and therefore the generalisability of our findings to other centres

and populations are uncertain. Further, our model was generated from a relatively modest sample size due to the relatively low prevalence of COVID-19 patients in the catchment population of the hospital, particularly during the early months of the pandemic. One advantage of using this single dataset from a large, tertiary hospital was that the hospital never became overwhelmed with patients, and therefore it is considered that patients received care according to what was felt to be clinically appropriate rather than according to what resources were available. It is also important to note that as the pandemic has evolved in the UK, there have been changes in both the clinical care of patients (notably with the routine inclusion of steroid therapy for patients requiring oxygen) and in the strains of the virus circulating. It is encouraging that the model continued to perform well in the Wave 2 validation data, but over time, changes such as these may influence the clinical picture of the disease, its severity and the risk factors for disease. It is likely therefore that the model will need to be updated as the pandemic evolves and the utilisation of routinely available data in this model makes this relatively simple to do.

The ongoing COVID-19 pandemic continues to affect the lives of many and to put extreme pressure on clinical services. We have developed and validated a dynamic prediction model with high discrimination of 48-hour in-hospital mortality in COVID-19 using routine clinical data that updates over the course of the illness and patient admission. This represents a significant advance on existing point-of-admission COVID-19 prediction models: it has the potential to inform patient management and resource planning and allocation in real-world settings. In doing so, this model could considerably improve both individual patient care, and the ability to manage pandemic response on a hospital wide scale.

### **Data availability**

The de-identified data that support the findings of this study are available from Cambridge University Hospitals but restrictions apply to the availability of these data, which were used under license for the current study, and so are not publicly available. Data are however available from the authors upon reasonable request with permission of Cambridge University Hospitals.

## **Acknowledgements**

Martin Wiegand was funded by the NIHR Cambridge Biomedical Research Centre [BRC-1215-20014]. Victoria L. Keevil was funded by the MRC/NIHR Clinical Academic Research Partnership Grant (CARP) [grant code MR/T023902/1]. Vince Taylor was funded by the Cancer Research UK Cambridge Centre. Effrossyni Gkrania-Klotsas was supported by the NIHR Clinical Research Network (CRN) Greenshoots Award. Brian D. M. Tom and Robert J. B. Goudie were funded by the UKRI Medical Research Council (MRC) [programme code MC\_UU\_00002/2] and supported by the NIHR Cambridge Biomedical Research Centre [BRC-1215-20014].

We thank Christopher Osuafor, Catriona Davidson, Alistair Mackett, Marie Goujon and Lelane Van Der Poel for assisting with the frailty sub-study.

The funders had no role in the design and conduct of the study; collection, management, analysis, and interpretation of the data; preparation, review, or approval of the manuscript; and decision to submit the manuscript for publication. The views expressed are those of the authors and not necessarily those of the NHS, the NIHR, the MRC, or the Department of Health and Social Care.

## **Author contributions**

**Conception:** JP, RJBG, SLC, EGK, CW and MW conceived the research project and designed the study.

**Data collection:** VT, MW, SLC and RJBG extracted and curated the dataset. VLK and DJH collected data.

**Analysis tools & Data interpretation:** MW, RJBG and BDMT analysed and contributed to the selection and creation of analysis tools. JP, CSW, EGK, DJH, VLK and BDMT interpreted the data and results.

**Implementation:** MW and RJBG performed the implementation and analysis of the proposed method.

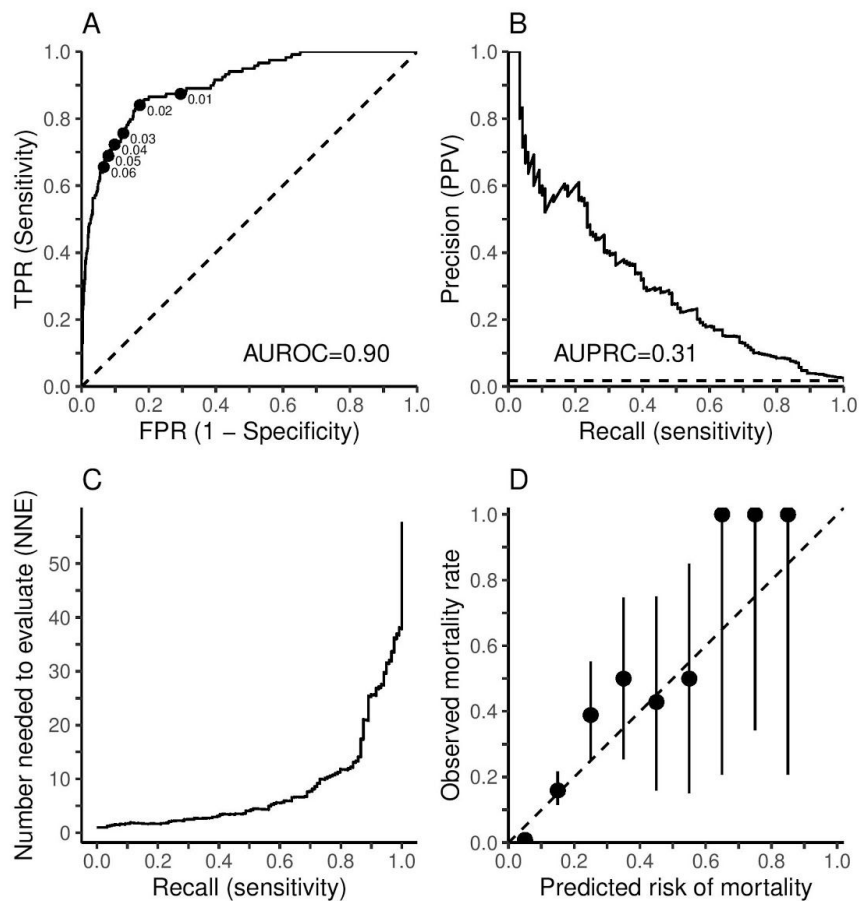

**Draft writing:** MW, CSW, EGK, SLC and RJBG wrote the initial draft. All authors contributed to substantively revising the article for important intellectual content.

### Approval of final submission

All authors approved of the final version of this script to be published, and are accountable for the work presented.

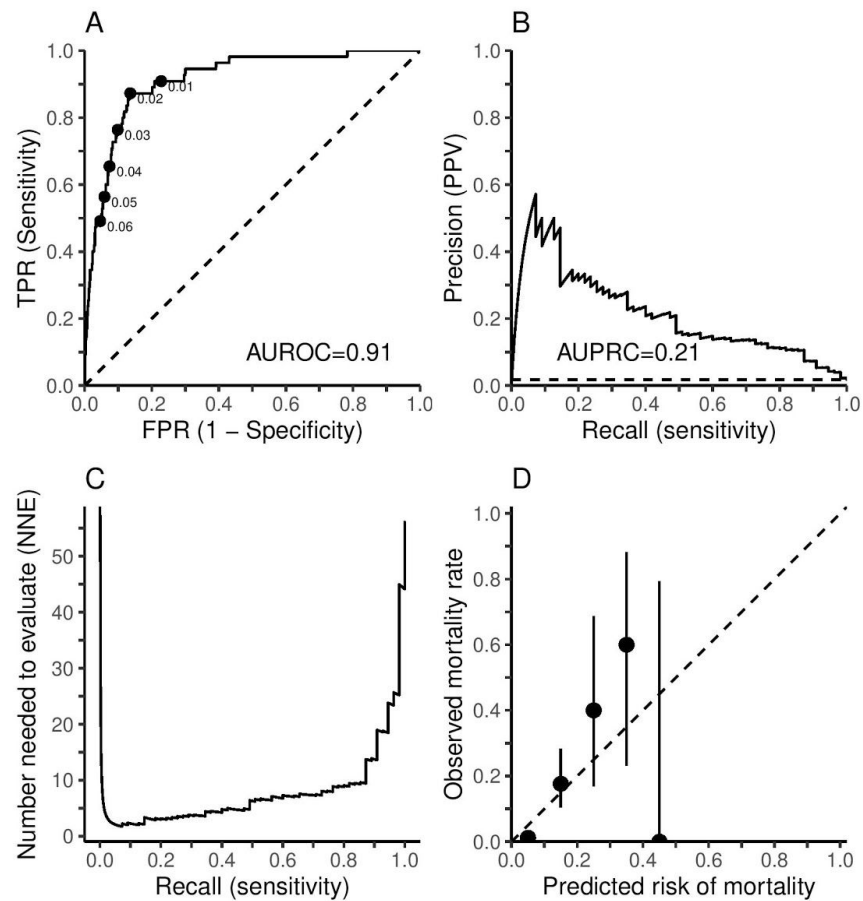

## Figures

**Figure 1.** Performance metrics for in-hospital mortality in the training dataset. (A) Receiver operator characteristic plot, with labels indicating the corresponding threshold and the dashed line indicating the line of no discrimination. (B) Precision-recall plot, with the 1.7% observed incidence indicated by the dashed line. (C) Number needed to evaluate against sensitivity. (D) Calibration plot (with 95% CI), by tenths of predicted risk, with the dashed line indicating perfect calibration.

**Figure 2.** Performance metrics for in-hospital mortality in the test dataset. (A) Receiver operator characteristic plot, with labels indicating the corresponding threshold and the dashed line indicating the line of no discrimination. (B) Precision-recall plot, with the 1.8% observed incidence indicated by the dashed line. (C) Number needed to evaluate against sensitivity. (D) Calibration plot (with 95% CI), by tenths of predicted risk, with the dashed line indicating perfect calibration.

## Tables

**Table 1:** Cohort demographics and clinical features in Wave 1 and Wave 2.

Characteristic	Wave 1 (training data set)	Wave 2 (test data set)
Admission dates	Mar 1, 2020 – Sep 12, 2020	Sep 13, 2020 – Jan 1, 2021
Number of patients	473	405
Female, n (%)	196 (41.4%)	203 (50.1%)
Age at admission, median [IQR], years	69 [55, 81]	61 [47, 77]
Admission BMI, median [IQR], kg/m <sup>a</sup>	25.7 [22.1, 29.9]	27.4 [23.4, 32]
Clinical Frailty Score at admission for over 65 year olds, median [IQR]	5 [3, 6]	5 [4,6]
Nosocomial infection, n (%)	36 (7.6%)	37 (9.2%)
Length of stay, median [IQR], days	10.8 [3.9, 19.8]	3.8 [1.0,12.1] <sup>b</sup>
<b>Ethnicity, number (%)</b>		
White	354 (74.8%)	255 (63.3%)
Asian	24 (5.1%)	26 (6.5%)
Black	10 (2.1%)	6 (1.5%)
Other	11 (2.3%)	23 (5.7%)
Prefer not to say/ Not recorded	74 (15.6%)	93 (23.1%)
<b>Outcomes, number (%)</b>		
Deceased in-hospital <sup>c</sup>	99 (20.9%)	41 (10.1%)
Transferred for ECMO	5 (1.1%)	0 (0%)

Discharged alive	369 (78.0%)	277 (68.0%)
Remain in hospital on Jan 3, 2021	0 (0%)	87 (21.4%)
<b>Support / treatments received during hospital stay, number (%)</b>		
ICU admission	103 (21.8%)	69 (17.0%)
Invasive mechanical ventilation	82 (17.3%)	48 (11.9%)
Cardiovascular support	86 (18.2%)	47 (11.6%)
Renal replacement therapy	32 (6.8%)	10 (2.5%)
Steroids	125 (26.4%)	185 (45.7%)
<b>Admission observations <sup>a</sup>, median [IQR]</b>		
Mean arterial pressure, mmHg	86 [76, 96]	87 [79, 98]
Heart rate, beats/min	83 [72, 93]	82 [72, 92]
Temperature, degrees celsius	37.2 [36.7, 37.8]	37 [36.6, 37.4]
Respiratory rate, breaths/min	19 [17, 22]	18 [17, 20]
Oxygen saturation (SpO <sub>2</sub> ), %	96 [94, 97]	96 [94, 98]
SpO <sub>2</sub> /FiO <sub>2</sub> ratio	448 [337, 457]	452 [346, 462]
<b>Admission blood results <sup>a</sup>, median [IQR]</b>		
Urea, mmol/L	7.8 [5.0, 11.8]	6.3 [5.0, 10.1]
Creatinine, $\mu$ mol/L	75 [61, 106]	70 [55, 93]
Sodium, mmol/L	137 [134, 140]	137 [134, 139]
CRP, mg/L	87 [39, 178]	53 [24, 94]
WCC, 10 <sup>9</sup> /L	6.9 [4.9, 9.3]	6.3 [4.7, 9.5]

Neutrophils, 10 <sup>9</sup> /L	5.4 [3.6, 7.8]	4.8 [3.3, 7.8]
Lymphocytes, 10 <sup>9</sup> /L	0.8 [0.5, 1.2]	0.8 [0.5, 1.1]
D-dimer, ng/ml	334 [177, 682]	275 [168, 661]
Troponin, ng/L	20.0 [8.3, 63.6]	11.0 [4.0, 47.0]
pH	7.43 [7.37, 7.46]	7.44 [7.40, 7.46]
IL-6, pg/ml	15.1 [5.3, 40.2]	17.0 [5.2, 30.2]

<sup>a</sup> First after positive SARS-CoV-2 test result for hospital-acquired COVID-19 cases

<sup>b</sup> For Wave 2, includes stays completed by Jan 3, 2021 only. Note that because follow-up continued until January 3 2021, the outcome during the 48-hour prediction horizon was known for all landmark times up to January 1 2021, and so patients remaining in hospital at the study end-date could be included in the validation.

<sup>c</sup> Total in-hospital mortality including those patients who were classified as “end of life” prior to death.

**Table 2.** Final model coefficients

Predictor	Coefficients	
	When recorded	If unrecorded
Age <75 years, at admission	-0.516	–
Age <80 years, at admission	-0.245	–
Clinical Frailty Score, at admission	0.0678	0.0514
Heart rate, beats/min, mean during last 24h	0.00282	–
Respiratory rate, breaths/min, minimum during last 24h	0.102	–
S/F ratio, minimum during last 24h	-0.0116	–
WCC, 10 <sup>9</sup> /L, most recent measurement during last 48h	0.00651	-0.00151
Acidosis, 7.35 - (lowest pH during last 24h), or 0 if all above 7.35	3.18	0.220
IL-6, pg/ml, most recent measurement during last 48h	0.000166	-0.0218

## Supplementary Information

**Table S1.** Complete list of candidate predictors, summary statistics and missingness for the development dataset.

Marker	Unit	Summary measure/coding	Summary across landmark times <sup>a</sup>	Missingness across landmark times <sup>b</sup>
<b>Demographics</b>				
Age at admission	Years		69 [55,81]	– (0%)
		<45	517(7.6%)	–
		<50	853 (12.5%)	–
		<55	1386 (20.2%)	–
		<60	2164 (31.6%)	–
		<65	2779 (40.6%)	–
		<70	3371 (49.2%)	–
		<75	4284 (62.6%)	–
		<80	5236 (76.5%)	–
		<85	5857 (85.6%)	–
		<90	6315 (92.3%)	–
		<95	6670 (97.4%)	–
Sex	Female/ Male		41.4% / 58.6%	– (0%)
Ethnicity		Not included		
	Whiteyes/no	White British/ White Irish/ Other white background	5215 (76.2%)	– (16.3%)
	Asianyes/no	Asian Indian/ Asian Pakistani/ Asian Bangladeshi/ Other Chinese/ Other Asian background	225 (3.3%)	– (16.3%)

Black	yes/no	Black Caribbean/ Black African/ Other Black background	155 (2.3%)	– (16.3%)
Other	yes/no	Other ethnic group/ Mixed white and black caribbean/ Mixed white and black African/ Mixed White and Asian/ Other mixed background	137 (2.0%)	– (16.3%)
Body Mass Index	kg/m <sup>2</sup>	Not included	27.3 [22.5, 30.3]	– (6.1%)
Underweight	kg/m <sup>2</sup>	18.5 - (Most recent BMI), or 0 if most recent BMI above 18.5	93.5% = 0 After excluding zero: 1.4 [0.5, 1.9]	– (6.1%)
Overweight	kg/m <sup>2</sup>	(Most recent BMI) - 25, or 0 if most recent BMI below 25	38% = 0 After excluding zero: 4.4 [2.3, 9.1]	– (6.1%)
Clinical Frailty Scale <sup>c</sup>		Value	5 [3, 6]	– (54.5%)
<b>Comorbidities</b>				
Asthma	yes/no	Documented history of	780 (11.4%)	–
Dementia	yes/no	Documented history of	353 (5.2%)	–
Diabetes	yes/no	Documented history of	1233 (18.0%)	–
Chronic heart	yes/no	Documented history of	1260 (18.4%)	–

disease				
Hypertension	yes/no	Documented history of	2193 (32.0%)	
Immunocompromised	yes/no	Documented history of	80 (1.1%)	
Chronic liver disease	yes/no	Documented history of	640 (9.4%)	
Non-haematological malignancy	yes/no	Documented history of	576 (8.4%)	
Haematological malignancy	yes/no	Documented history of	284 (4.1%)	
Chronic kidney disease	yes/no	Documented history of	502 (7.3%)	
Respiratory disease	yes/no	Documented history of	833 (12.2%)	
Stroke	yes/no	Documented history of	220 (3.2%)	
<b>Observations</b>				
Heart rate (HR)	Beats/min	24h mean	83 [73, 93]	17.3 (0.0%)
		24h min	72 [63, 82]	
		24h max	94 [83, 106]	
		Trend	0 [-4.5, 4]	
Mean arterial pressure	mmHg	24h mean	86 [79, 94]	17.1 (0.0%)
		24h min	74 [66, 83]	
		24h max	100 [91, 109]	
		Trend	0.0 [-0.4, 0.4]	
Temperature	Degrees	24h mean	37.0 [36.7, 37.3]	9.3 (0.0%)

	Celsius	24h min	36.4 [36.1, 36.7]	
		24h max	37.5 [37.1, 38.1]	
		Trend	0 [-0.3, 0.2]	- (6.3%)
Respiratory Rate (RR)	Breaths/min	24h mean	18.5 [17, 21]	18.8 (0.0%)
		24h min	16 [15, 18]	
		24h max	20 [19, 26]	
		Trend	0 [-1, 1]	- (6.3%)
S/F ratio		24h mean	431 [325, 456]	12.8 (0.0%)
		24h min	392 [250, 448]	
		24h max	457 [443, 467]	
		Trend	0 [-7.0, 7.4]	- (6.3%)
P/F ratio	mmHg	24h mean	184 [136, 250]	1.5 (77.9%)
		24h min	140 [98, 201]	
		24h max	229 [171, 310]	
		Trend	2 [-18, 24]	- (80.3%)
Glasgow coma scale (GCS)	Lowest	<9	33.8%	-
	GCS in the last 24h	<12	47.0%	-
<b>Laboratory tests</b>				
Urea	mmol/L	Most recent measurement during last 48h	8.8 [5.6, 14.1]	0.9 (38.0%)
Creatinine	$\mu$ mol/L	Most recent measurement during last 48h	70 [52, 106]	0.9 (25.8%)
		Trend	-1 [-7, 4]	- (43.4%)
Sodium	mmol/L	Not included	138.6 [135.5, 142]	2.7 (24.8%)
		Trend	0.0 [-1.0, 1.5]	- (41.9%)
Hyponatraemia	Na < 135 mmol/L	135 - (lowest sodium during last 24h), or 0 if all above 135	82% = 0 After excluding zero: 2 [1, 4]	2.7 (24.8%)

Hypernatraemia	Na > 145 mmol/L	(highest sodium during last 24h) - 145, or 0 if all below 145	85.2% = 0 After excluding zero: 3.8 [2, 6.2]	
Potassium	mmol/L	Most recent measurement during last 24h	4.1 [3.7, 4.4]	2.7 (25.0%)
		Trend	0 [-0.2, 0.2]	- (42.1%)
Albumin	g/L	Most recent measurement during last 48h	24 [20, 28]	1.2 (33.6%)
Alanine Transaminase (ALT)	U/L	Most recent measurement during last 48h	36 [22, 61]	0.7 (37.2%)
Alkaline phosphatase (ALP)	U/L	Most recent measurement during last 48h	100 [73, 149]	2.3 (19.8%)
Bilirubin	$\mu$ mol/L	Most recent measurement during last 48h	8 [5, 13]	0.7 (37.4%)
Lactate dehydrogenase (LDH)	U/L	Most recent measurement during last 48h	335 [261, 436]	0.2 (80.5%)
C-reactive protein (CRP)	mg/L	Most recent measurement during last 48h	56 [22, 131]	1.6 (12.8%)
		Trend	0 [-0.2, 0.3]	- (45.9%)
Procalcitonin (PCT)	ng/ml	Most recent measurement during last 48h	0.24 [0.08, 0.83]	0.2 (84.4%)
Ferritin	$\mu$ g/L	Most recent	726 [336, 1427]	0.3 (76.6%)

		measurement during last 48h		
Haemoglobin	g/L	Most recent measurement during last 48h	104 [89, 122]	5.4 (12.4%)
		Trend	-1 [-5, 3]	- (43.9%)
White cell count (WCC)	10 <sup>9</sup> /L	Most recent measurement during last 48h	7.9 [5.7, 10.6]	1.6 (12.7%)
		Trend	0 [-1, 1]	- (46.1%)
Neutrophils	10 <sup>9</sup> /L	Most recent measurement during last 48h	5.7 [3.9, 8.2]	1.6 (13.4%)
Lymphocytes	10 <sup>9</sup> /L	Most recent measurement during last 48h	1.1 [0.7, 1.5]	1.6 (13.4%)
Neutrophil-Lymphocytes ratio	Ratio	Most recent measurement during last 48h	5.4 [3.2, 9.5]	1.6 (13.5%)
Eosinophils	10 <sup>9</sup> /L	Most recent measurement during last 48h	0.1 [0.02, 0.28]	1.6 (14.1%)
Monocytes	10 <sup>9</sup> /L	Most recent measurement during last 48h	0.45 [0.3, 0.64]	1.6 (13.5%)
Platelets	10 <sup>9</sup> /L	Most recent measurement during last 48h	280 [193, 387]	1.6 (12.8%)
		Trend	3 [-17, 26]	- (46.3%)
Red cell distribution width (RDW)	%	Most recent measurement during last 48h	15.1 [14, 16.4]	1.6 (13.3%)
Prothrombin Time	sec	Most recent	13.3 [12.5, 14.5]	0.84 (52.6%)

		measurement during last 48h		
Activated partial thromboplastin time (APTT)	sec	Most recent measurement during last 48h	32.3 [29.6, 35.3]	0.84 (53.8%)
D-Dimer	ng/ml	Most recent measurement during last 48h	552 [284, 1677]	0.4 (71.9%)
Troponin	ng/L	Most recent measurement during last 48h	17 [5.6, 48.7]	0.3 (80.5%)
Interferon Gamma (IG)	pg/ml	Most recent measurement during last 48h	0.9 [0.9, 2.5]	0.2 (84.2%)
TNF-Alpha (TNFA)	pg/ml	Most recent measurement during last 48h	12.3 [8.3, 18.2]	0.2 (84.2%)
Interleukin-1 beta (IL-1)	pg/ml	Most recent measurement during last 48h	0.5 [0.3, 0.9]	0.2 (84.2%)
Interleukin-6 (IL-6)	pg/ml	Most recent measurement during last 48h	13.6 [4.7, 31.9]	0.3 (84.0%)
Interleukin-10 (IL-10)	pg/ml	Most recent measurement during last 48h	1.88 [0.7, 4.4]	0.2 (84.2%)
Interleukin ratio (IL-ratio, IL6/IL10)	Ratio	Most recent measurement during last 48h	7.6 [2.9, 20.1]	0.2 (84.3%)
Lactate	mmol/L	Most recent measurement during last 48h	1.3 [1.0, 1.7]	3.7 (60.4%)

pH – arterial or (venous + 0.03)		Not included	7.41 [7.36, 7.44]	1.9 (66.4%)
Acidosis	pH-value < 7.35	7.35 - (lowest pH during last 24h), or 0 if all above 7.35	67.1% = 0 After excluding zero: 0.06 [0.028,0.107]	1.9 (66.4%)
Alkalosis	pH-value > 7.45	(Highest pH during last 24h) - 7.45, or 0 if all below 7.45	66.8% = 0 After excluding zero: 0.024 [0.011, 0.039]	
<b>Treatments, interventions and level of care</b>				
Visited ICU	yes/no	During last 24h	1789 (26.1%)	–
Mechanically ventilated	yes/no	During last 24h	1420 (20.7%)	–
Cardiovascular support	yes/no	During last 24h	705 (10.3%)	–
Renal replacement therapy	yes/no	During last 24h	348 (5.1%)	–
Steroids (oral or intravenous; dexamethasone, hydrocortisone, prednisolone, methylprednisolone)	yes/no	Ever during this hospital visit up to now	2770 (40.5%)	–

<sup>a</sup> For yes/no items shown as number (%) across landmark times; for quantitative items shown as median [IQR] across landmark times

<sup>b</sup> Shown as mean number of measurements per landmark (% landmarks with no measurement)

° For 45 patients for whom no CFS score had been recorded by the treating team, a consultant or specialist registrar in Geriatric Medicine reviewed the clinical records and assigned a CFS score using only information recorded at the time of admission.

**Table S2.** ICD-10 codes used to identify comorbidities.

<b>Diagnosis</b>	<b>ICD-10 codes</b>	<b>Description</b>
<b>Hypertension</b>	I10	Essential hypertension
	I11	Hypertensive heart disease
	I12	Hypertensive renal disease
	I13	Hypertensive heart and renal disease
	I15	Secondary hypertension
<b>Diabetes</b>	E10	Type 1 diabetes mellitus
	E11	Type 2 diabetes mellitus
	E12	Malnutrition-related diabetes mellitus
	E13	Other specified diabetes mellitus
	E14	Other unspecified diabetes mellitus
<b>Chronic liver disease</b>	K70	Alcoholic liver disease
	K71	Toxic liver disease
	K72	Hepatic failure, not elsewhere classified
	K73	Chronic hepatitis, not elsewhere classified
	K74	Fibrosis and cirrhosis of the liver
	K75	Other inflammatory diseases of the liver
	K76	Other diseases of the liver
	K77	Liver disorders in disease classified elsewhere
<b>Asthma</b>	J45	Asthma
<b>Non-haematological malignancy</b>	C0	Malignant neoplasm of lip
	C1	Malignant neoplasm of base of tongue
	C2	Malignant neoplasm of other unspecified parts of tongue
	C3	Malignant neoplasm of gum
	C4	Malignant neoplasm of floor of mouth
	C5	Malignant neoplasm of palate
	C6	Malignant neoplasm of other and unspecified parts of mouth
	C7	Malignant neoplasm of parotid gland

<b>Haematological malignancy</b>	C8	Malignant neoplasm of other and unspecified major salivary glands
	C9	Malignant neoplasm of tonsil
<b>Stroke</b>	I63	Cerebral infarction
	I65	Occlusion and stenosis of precerebral arteries, not resulting in cerebral infarction
	I66	Occlusion and stenosis of cerebral arteries, not resulting in cerebral infarction
<b>Chronic kidney disease</b>	N18.1-N18.5	Chronic kidney disease stage 1-5
	N18.9	Chronic kidney disease, unspecified
	I13	Hypertensive and renal disease
<b>Chronic heart disease</b>	I20	Angina pectoris
	I21	Acute myocardial infarction
	I22	Subsequent myocardial infarction
	I23	Certain current complications following acute myocardial infarction
	I24	Other acute ischaemic heart diseases
	I25	Chronic ischaemic heart disease
	I34	Nonrheumatic mitral valve disorders
	I35	Nonrheumatic aortic valve disorders
	I36	Nonrheumatic tricuspid valve disorders
	I37	Pulmonary valve disorders
	I42	Cardiomyopathy
	I43	Cardiomyopathy in diseases classified elsewhere
	I44	Atrioventricular and left bundle-branch block
	I50	Heart failure
<b>Immunocompromised</b>	D80	Immunodeficiency with predominantly antibody defects
	D81	Combined immunodeficiencies
	D82	Immunodeficiency associated with other major defects
	D83	Common variable immunodeficiency
	D84	Other immunodeficiencies
<b>Dementia</b>	F01	Vascular dementia
	F02	Dementia in other diseases classified elsewhere

	F03	Unspecified dementia
	G30, G31	Alzheimer disease & Other degenerative diseases of nervous system, not elsewhere classified
	F10.27	Alcohol dependence, with alcohol-induced persisting dementia
	F10.97	Alcohol use, unspecified with alcohol-induced persisting dementia
	F19.97	Other psychoactive substance use, unspecified with psychoactive substance-induced persisting dementia
<b>Respiratory disease</b>	I27	Other pulmonary heart diseases
	J6*-J7*	Lung diseases due to external agents
	J41	Simple and mucopurulent chronic bronchitis
	J42	Unspecified chronic bronchitis
	J43	Emphysema
	J44	Other chronic obstructive pulmonary disease
	J47	Bronchiectasis

**Table S3:** Baseline cumulative subdistribution hazards for mortality in the final model

Time after landmark (hours)	Cumulative subdistribution hazard	Time after landmark (hours)	Cumulative subdistribution hazard	Time after landmark (hours)	Cumulative subdistribution hazard	Time after landmark (hours)	Cumulative subdistribution hazard
1	0.00094	13	0.00852	25	0.02143	37	0.03339
