23 **Abstract:** 230 words

24 **Running headline:** Vitamin D, adverse COVID-19 outcomes and adiposity

25 **ABSTRACT (229 WORDS)**

26 **INTRODUCTION:** Coronavirus disease (COVID-19) is a global pandemic. Vitamin D (25-  
27 OHD) deficiency has been associated with susceptibility to infectious disease. In this  
28 study, the association between COVID-19 outcomes and 25-OHD levels in patients  
29 attending a COVID-19 reference center in Mexico City are examined.

30 **METHODS:** Consecutive patients with confirmed COVID-19 were evaluated. All patients  
31 underwent clinical evaluation (including outcomes), laboratory measurements (including  
32 25-OHD) and a thoracic computerized tomography (including the measurement of  
33 epicardial fat thickness). Low vitamin D was defined as levels  $<20\text{ng/mL}$  ( $<50\text{nmol/L}$ ) and  
34 severely low (or deficient) 25-OHD as a level  $\leq 12\text{ng/mL}$  ( $<30\text{nmol/L}$ )

35 **RESULTS:** Of the 551 patients included, low 25-OHD levels were present in 45.6% and  
36 severely low levels in 10.9%. Severely low 25-OHD levels were associated with mortality  
37 (HR 2.11, 95%CI 1.24-3.58,  $p=0.006$ ) but not with critical COVID-19 (OR 0.97, 95%CI  
38 0.94-0.99,  $p=0.042$ ), adjusted for age, sex, body-mass index and epicardial fat. Using  
39 model-based causal mediation analyses the increased risk of COVID-19 mortality  
40 conferred by 25-OHD levels was partly mediated by its effect on D-dimer and cardiac  
41 ultrasensitive troponins. Notably, increased risk of COVID-19 mortality conferred by low  
42 vitamin D levels was independent of BMI and epicardial fat.

43 **CONCLUSION:** Vitamin D deficiency ( $\leq 12\text{ng/mL}$  or  $<30\text{nmol/L}$ ), is independently  
44 associated with COVID-19 mortality after adjustment for visceral fat (epicardial fat  
45 thickness). Low 25-OHD may contribute to a pro-inflammatory and pro-thrombotic state,  
46 increasing the risk for adverse COVID-19 outcomes.

47 **Keywords:** Vitamin D, COVID-19, SARS-CoV-2, Adiposity, Severe disease

## 48 INTRODUCTION

49 Coronavirus Disease (COVID-19), caused by the novel coronavirus severe acute  
50 respiratory syndrome coronavirus 2 (SARS-CoV-2), is a global pandemic. SARS-CoV-2  
51 spreads primarily by close contact with respiratory droplets from infected individuals and  
52 contaminated surfaces (1-3). SARS-CoV-2 infects cells using the angiotensin converting  
53 enzyme-2 (ACE-2) receptor; infection can produce an interstitial pneumonia that may  
54 progress to acute respiratory distress syndrome (ARDS) and death (4-6).

55 Vitamin D (25-OHD) is a steroid hormone involved in essential physiological roles  
56 including preserving bone integrity, immunomodulation by stimulating innate immunity and  
57 tempering adaptive immunity, infectious disease prevention and cardiovascular health (7-  
58 9). It also acts on the renin angiotensin aldosterone (RAAS) system, inhibiting the  
59 angiotensin converting enzyme (ACE, 6). Several factors are known to influence vitamin D  
60 levels; lower levels are associated with ethnicity, variation in sun exposure due to higher  
61 latitudes, season, time of day, clothing, sunscreen use and skin pigmentation, age, lower  
62 sun exposure, obesity and chronic illnesses (10). The presence of obesity results in  
63 decreased bioavailability of vitamin D, which is probably related to sequestration into  
64 adipose tissue. Furthermore, higher visceral fat content has been shown to be related to a  
65 higher incidence of vitamin D deficiency (11).

66 Low levels of 25-OHD have been associated with increased susceptibility to infectious  
67 disease, particularly respiratory tract infections (12-14). Several studies have explored the  
68 relationship between COVID-19 and vitamin D levels (15-18); however, concerns  
69 regarding residual confounding and the lack of mechanistic interpretations for the  
70 association of low 25-OHD levels with adverse COVID-19 outcomes requires further  
71 studies. Obesity and ethnicity are important risk factors for severe disease, and are also  
72 known to modulate vitamin D levels. This may be particularly relevant in Mexico, where

73 high rates of diabetes and obesity have been associated with an increased risk of severe  
74 COVID-19 (19). In this study, the association between COVID-19 outcomes and 25-OHD  
75 levels in patients attending a COVID-19 reference center in Mexico City is evaluated. We  
76 aim to identify determinants of 25-OHD levels in COVID-19 patients and develop causal-  
77 mediation models to propose mechanisms by which Vitamin D may lead to increased  
78 COVID-19 mortality.

## 79 **METHODS**

### 80 *Study population*

81 This study included consecutive patients evaluated at the Instituto Nacional de Ciencias  
82 Médicas y Nutrición Salvador Zubirán, a COVID-19 reference center in Mexico City  
83 between 17th March and 31st May 2020. Subjects were initially assessed at triage and  
84 required either ambulatory or in-hospital care for COVID-19 (confirmed with computerized  
85 tomography (CT) and/or via RT-qPCR test from nasopharyngeal swabs. All patients had  
86 moderate to severe disease as defined by National Institute of Health criteria (*Moderate*  
87 *Illness*: Evidence of lower respiratory disease during clinical assessment or imaging and  
88 who have saturation of oxygen (SpO<sub>2</sub>) ≥94% on air. *Severe Illness*: SpO<sub>2</sub> <94% on air, a  
89 ratio of arterial partial pressure of oxygen to fraction of inspired oxygen (PaO<sub>2</sub>/FiO<sub>2</sub>) <300  
90 mm Hg, respiratory frequency >30 breaths/min, or lung infiltrates >50%). Subjects  
91 underwent a chest CT, and a radiologist determined the degree of pulmonary parenchymal  
92 disease and assessed epicardial fat thickness as a proxy for visceral fat. In addition, a  
93 medical history, anthropometric measurements and laboratory tests were obtained,  
94 including 25 hydroxy-vitamin D (25(OH)-D). The electronic files of each patient were  
95 reviewed to document the outcomes during hospitalization. All proceedings were approved  
96 by the research and ethics committee of the INCMNZ (Ref 3383) and informed consent  
97 was waived due to the nature of the study.

98 *Laboratory and clinical measurements*

99 Clinical variables and laboratory measures were obtained at the time of initial evaluation.  
100 Physical examination included: weight, height, body mass index (BMI, calculated as weight  
101 in kilograms divided by squared height in meters), pulse oximeter saturation (SpO<sub>2</sub>),  
102 respiratory rate (RR), temperature and arterial blood pressure (BP). Laboratory  
103 measurements included: full blood count and chemistry panel including liver function tests,  
104 C-reactive protein (CRP), fibrinogen, D-dimer, ferritin, troponin I (TPNI), erythrocyte  
105 sedimentation rate (ESR) and procalcitonin levels. The blood samples were processed in  
106 the central laboratory of the Instituto Nacional de Ciencias Médicas y Nutrición Salvador  
107 Zubirán, Vitamin D (25-hydroxivitamin D) was measured by chemiluminescence using the  
108 Abbott Architect I2000 equipment. Low levels of vitamin D were defined as <20ng/mL (<50  
109 nmol/L) and severely low (or deficiency) as a level <12ng/mL (<30nmol/L) (6-9).

110 *Epicardial fat measurements*

111 All patients underwent unenhanced CT scans including low-dose CT and two ultra-low-  
112 dose CT protocols with commonly reported imaging features of COVID-19 pneumonia.  
113 The thoracic CT was performed using a 64-slice scanner (GE MEDICAL SYSTEMS  
114 Revolution EVO). Epicardial adipose tissue (EAT) thickness was measured at 3 points  
115 (right atrioventricular fossa, left atrioventricular fossa, and anterior interventricular fossa) in  
116 the reformatted 4-chamber view using the multiplanar reconstruction (MPR) tool on the  
117 workstation (20, 21, 22). The maximum thickness of the EAT was determined from the  
118 surface of the myocardium to the pericardium (measured perpendicular to the  
119 pericardium). The measurements were made on 2 different occasions, obtaining a total of  
120 6 measurements; the average of them was used for all statistical analyses. Pericardial  
121 adipose tissue (PAT) was quantified with the volume measurement tool with the  
122 Carestream system of the workstation. The thickness of the thoracic subcutaneous

123 adipose tissue (TscAT) was measured from the anterior border of the sternum to the skin,  
124 at the level of the mitral valve in the axial plane of the tomography. The 80th gender-  
125 specific percentile of EAT thickness was obtained and used as the threshold to define  
126 increased EAT thickness. In addition, chest CT findings were recorded and used to  
127 evaluate severity of COVID infection.

#### 128 *COVID-19 outcomes*

129 Outcomes included mortality and critical disease (defined as the combination of mortality  
130 and need for mechanical ventilation /intubation). For time-to-event analyses, time from  
131 self-reported symptom onset prior to evaluation until last follow-up (censoring) or death,  
132 whichever occurred first was estimated.

#### 133 *Statistical analyses*

134 Cases with low and severely low vitamin D levels were analyzed using Student's t-test or  
135 Mann-Whitney U according to the variable distribution (parametric or non-parametric) for  
136 continuous variables. The chi-squared test was applied for categorical variables.  
137 Logarithmic, squared root and cubic root transformations were carried out to ensure  
138 variable symmetry prior to modeling. All statistical analyses were conducted using R 4.0.2.

#### 139 *Prediction of mortality and severe COVID-19*

140 Cox proportional risk regression analyses was used to investigate the association of  
141 vitamin D with mortality related to COVID-19. Univariate models and fully adjusted models  
142 were generated which included the following covariates: age, gender, BMI, C-reactive  
143 protein, D-dimer, ultrasensitive cardiac troponin, epicardial fat, T2D, CKD and oxygen  
144 saturation levels. An interaction effect was explored with BMI or BMI categories to rule out  
145 the differential impact of vitamin D adjusted for BMI. Model diagnostics were done using  
146 Schoenfeld residuals. Finally, the association of vitamin D with requirement for mechanical

147 ventilation or the composite of critical COVID-19 was explored using logistic regression  
148 analyses adjusted for the aforementioned covariates.

#### 149 *Predictors of vitamin D levels*

150 Linear regression analyses were fitted to identify predictors of log-transformed vitamin D  
151 levels in patients with COVID-19, and model selection was carried out using minimization  
152 of the Bayesian Information Criterion (BIC). Logistic regression models were also fitted  
153 using a dummy variable which defined low and severely low vitamin D to identify predictors  
154 for these categories and again model selection was conducted using BIC. Finally, model  
155 diagnostics for linear regression were conducted using residual analyses and the Hosmer-  
156 Lemeshow test for logistic regression analyses.

#### 157 *Causal mediation models*

158 Finally, to explore whether variables which are influenced by Vitamin D levels may act as a  
159 mediator of the risk conferred by Vitamin D on COVID-19 severity, model-based causal  
160 mediation analyses were developed: D-dimer and ultrasensitive cardiac troponins were  
161 proposed as mediators of the effect of Vitamin D on COVID-19 mortality. All mediation  
162 analyses were performed using the mediation R package; to permit inference to obtain a  
163 95% confidence interval using bias-corrected accelerated non-parametric bootstrap. To  
164 demonstrate the sequential ignorability assumption, a sensitivity analysis was run to  
165 demonstrate residual confounding by varying the correlation between the residuals of both  
166 the outcome and the moderator models. Statistical analyses were performed using R  
167 software version 4.0.3. A p value <0.05 was considered statistically significant

## 168 **RESULTS**

### 169 *Study population*

170 This study included 551 patients with confirmed COVID-19 (with compatible computerized  
171 tomography findings and/or positive RT-qPCR test from nasopharyngeal swabs) and

172 vitamin D measurements. The mean age of participants was  $51.92 \pm 13.74$  years, with a  
173 male predominance ( $n=355$ , 64.4%), and a mean BMI of  $30.05 \pm 5.72$ . Median follow-up  
174 was 15.0 days (IQR 10.0-20.0) and 445 patients required hospitalization (81.1%). Overall,  
175 93 patients received invasive mechanical ventilation (16.88%) and 116 in-hospital deaths  
176 (21.1%) were recorded. Type 2 diabetes (T2D) was present in 146 patients (26.9%), 219  
177 patients had obesity (42.7%) and 217 were overweight (42.4%). Mean vitamin D levels  
178 were  $21.78 \pm 9.01$  and vitamin D levels below 20ng/mL were present in 251 subjects  
179 (45.6%) (**Table 1**). Extremely low vitamin D levels ( $\leq 12$ ng/mL) were observed in 59  
180 patients (10.7%) (**Table 1 supplementary material**).

#### 181 *Determinants of Vitamin D levels amongst patients with COVID-19*

182 The pathophysiological adaptations to COVID-19 may be predictive of low vitamin D  
183 levels. To this end, determinants of low vitamin D in COVID-19 were sought in an attempt  
184 to develop a mechanistic explanatory model for this relationship. Subjects with low vitamin  
185 D levels ( $< 20$ mg/dl) were more likely to be female, have type 2 diabetes, higher HbA1c,  
186 D-dimer and ferritin levels and lower oxygen saturation, albumin and C-reactive protein.  
187 Using linear regression, a lower log-transformed vitamin D level was independently  
188 associated with female gender, higher log-transformed ultrasensitive cardiac troponin,  
189 higher log-transformed D-dimer, higher log-transformed epicardial fat area, and lower C-  
190 reactive protein levels (**Table 2**). When exploring a model to detect low vitamin D levels,  
191 there was a significantly higher odds for log-transformed D-dimer levels (OR 1.31, 95%CI  
192 1.06-1.63); lower odds were associated with male gender (OR 0.45, 95%CI 0.31-0.65),  
193 higher oxygen saturation levels (OR 0.98, 95%CI 0.97-0.99) and higher C-reactive protein  
194 values (OR 0.75, 95%CI 0.61-0.92), adjusted for age, and log-transformed epicardial fat.  
195 There was no association between days from symptom onset and vitamin D levels at  
196 admission.

197 *Vitamin D levels and COVID-19 mortality*

198 Overall, vitamin D levels were significantly lower when comparing non-fatal to fatal COVID-  
199 19 cases ( $22.41 \pm 9.34$  vs.  $19.44 \pm 67.19$ ,  $p < 0.001$ ). When assessing risk related to the  
200 association between mortality and vitamin D levels using Cox regression, a 1-unit increase  
201 in vitamin D levels was associated with a decreased risk of COVID-19 mortality.  
202 Interestingly, when stratifying cases according to gender, the difference in vitamin D levels  
203 between fatal and non-fatal cases was greater in women compared to men and lower in  
204 cases with obesity (**Figure 1**). When the mortality models were adjusted for age, gender,  
205 BMI, and C-reactive protein, CKD and T2D the observed association between vitamin D  
206 levels and a decrease in COVID-19 mortality persisted (**Table 3**). There was no significant  
207 interaction with BMI, (as a continuous variable or categorized) in normal weight,  
208 overweight and obese with vitamin D levels. Using post-estimation simulation to predict  
209 risk associated with changes in vitamin D levels using the simPH R package, there was a  
210 steady decrease in risk attributable to increasing vitamin D concentrations using vitamin D  
211  $< 20 \text{ ng/mL}$  and  $\leq 12 \text{ ng/mL}$  as thresholds (**Figure 2**).

212 *Vitamin D and critical COVID-19*

213 When assessing the impact of vitamin D on the risk of invasive mechanical ventilation  
214 there was no significant association even after adjustment for age, gender, BMI, C-reactive  
215 protein, CKD or T2D status (OR 0.986, 95%CI 0.957-1.015,  $p = 0.366$ ). However, when  
216 assessing the composite of critical COVID-19 using logistic regression models, lower  
217 vitamin D levels were associated with critical COVID-19 (OR 0.97, 95%CI 0.94-0.99,  
218  $p = 0.042$ , adjusting by age, gender, BMI, C-reactive protein, D-dimer, CKD, SpO<sub>2</sub> or T2D  
219 status).

220 *Causal mediation models*

221 Finally, model-based causal mediation models were developed to assess whether the  
222 effect of vitamin D (E) on increased mortality risk (Y) was mediated through changes in  
223 variables identified in **Table 2** (M), adjusted for age, gender, BMI and epicardial fat. The  
224 direct effect of vitamin D on increased mortality risk was significant ( $\Delta_{E \rightarrow Y}$  -0.144, 95%CI -  
225 0.069, -0.010) and the indirect effect of vitamin D, mediated by increase D-dimer levels  
226 ( $\Delta_{E \rightarrow MY}$  -0.035, 95%CI -0.164, -0.010), represented 19.3% (95%CI 9.5-77.0%) of the  
227 overall association of vitamin D on mortality. A similar scenario was observed for cardiac  
228 troponins, whereby both the direct effect of vitamin D on mortality ( $\Delta_{E \rightarrow Y}$  -0.133, 95%CI -  
229 0.150, -0.020) and the indirect effect mediated by ultrasensitive cardiac troponins ( $\Delta_{E \rightarrow MY}$  -  
230 0.047, 95%CI -0.085, -0.020), were significant and represented 26.2% (95%CI 14.9-  
231 73.0%) of the overall effect of vitamin D on mortality. Notably, there were no significant  
232 causal mediation models for either BMI or epicardial fat, here there was only a direct effect  
233 on mortality, independent of vitamin D levels.

## 234 **DISCUSSION**

235 In this study, the association between vitamin D levels and severity of COVID-19 was  
236 explored in a Mexican population. Severely low levels of vitamin D (deficiency) showed a  
237 clear association with mortality, even after adjusting for confounders, including epicardial  
238 fat as a proxy of visceral fat and BMI. A vitamin D level <20ng/mL (<50nmol/L), showed a  
239 strong negative predictive value, suggesting that when levels are adequate, the probability  
240 of mortality is low. Furthermore, the increased risk of mortality from COVID-19 was partly  
241 mediated by the effect of vitamin D on markers of disease severity, such as D-dimer and  
242 ultrasensitive cardiac troponins, independent of BMI and epicardial fat (these showed  
243 effects on COVID-19 mortality independent of vitamin D levels). This suggests that vitamin  
244 D may be a marker of an impaired response to infection within the pulmonary epithelium,  
245 in particular in those with severe deficiency (23).

246 Several studies have explored the relationship between COVID-19 and vitamin D levels  
247 (15-17, 24). These include those examining vitamin D levels and risk of infection and those  
248 examining an association with severity of COVID-19. Higher levels of IL-6 were observed  
249 in the vitamin D deficient group suggesting a greater inflammatory response in these  
250 patients (18). A recent systematic review and meta-analysis reported that vitamin D  
251 deficiency was not associated with increased risk of infection, but severe cases presented  
252 with greater vitamin D deficiency compared with mild cases. Vitamin D deficiency has  
253 been associated to increased hospitalization and mortality risk from COVID-19 (19).

254 Physiological mechanisms by which vitamin D exerts a protective function include  
255 enhanced innate immunity including augmentation of physical barriers to infection and  
256 optimization of adaptive immunity (25). Adequate vitamin D levels favor protective tissue  
257 maintenance, preserving tight, gap and adherens junctions, all of which are disturbed by  
258 viruses (26). Calcitriol (1,25 OH D) induces production of cathelicidins, LL-37 and beta-  
259 defensins, proteins associated with viral surface disruption and reduced viral replication  
260 rates, lower pro-inflammatory cytokine (e.g. tumor necrosis factor alpha, interleukin-6)  
261 accumulation in target tissues such as the lungs and increased anti-inflammatory cytokine  
262 concentrations that defend against viral infections (27). In addition, vitamin D enhances  
263 macrophage phagocytosis and efferocytosis (allowing removal of cellular debris preventing  
264 further inflammation), and regulation of the macrophage oxidative burst (eliciting a more  
265 potent and efficient oxidative surge) (24).

266 Vitamin D also has a modulatory effect on the inflammatory response caused by COVID-  
267 19. It curbs adaptive immunity by inhibiting B cell proliferation, differentiation and  
268 production of antibodies and plays a role in regulation the T cell phenotype (28). Vitamin D  
269 suppresses helper T cells (Th)1 proliferation, thus decreasing the synthesis of cytokines  
270 such as interferon-gamma, interleukin-2 and interleukin-10 (6) (27, 29) This reduction in

271 cytokines, suppresses antigen presentation on dendritic cells and diminishes T lymphocyte  
272 recruitment and proliferation. Thus, there is a shift in the adaptive immune response from  
273 Th1 to a more regulatory Th2 response, characterized by an increase in expression of Th2  
274 associated cytokines (IL-4, IL-10) (30, 31). This may attenuate the quantity of pro-  
275 inflammatory cytokines that are associated with severe infection (32) In addition, vitamin D  
276 induces ACE 2 expression, and suppresses the angiotensin-renin system, thus reducing  
277 levels of proinflammatory angiotensin II. Hence, vitamin D deficiency, could potentiate the  
278 cytokine storm perpetuating a pro-inflammatory state and worsening pulmonary outcomes  
279 (33). Finally, thrombotic complications are common in such patients; vitamin D is also  
280 involved in the regulation of thrombotic pathways (29). In our study, low vitamin D levels in  
281 COVID-19 patients were related to inflammatory, pro-thrombotic and metabolic markers of  
282 severity, confirming observations from previous studies.

283 Adverse COVID-19 outcomes have been linked to the ethnic origin of the population under  
284 study; this has also been associated with the presence of vitamin D deficiency. Asians,  
285 African Americans, and ethnic minorities are at an increased risk of mortality from COVID-  
286 19 (34). This may partly be due to a decrease in the production of vitamin D dependent on  
287 UV rays. This is related to the skin levels of melanin present in these populations and on  
288 the unequal distribution of poverty and cardiometabolic disease rates across such  
289 ethnicities. This finding is relevant and may explain lower vitamin D levels and severity of  
290 COVID-19 in México in a previous study (35). Previous reports in similar populations,  
291 including Hispanics, have shown higher risk of SARS-CoV-2 infection, compared to  
292 Caucasian population (36).

293 Currently, routine vitamin D supplementation in hospitalized patients with COVID-19 is not  
294 recommended (37). A recent pilot study showed that administration of a high dose of  
295 calcifediol or 25-hydroxyvitamin D, significantly reduced the need for intensive care in

296 hospitalized patients (38). The authors speculate that calcifediol may reduce severity of  
297 the disease. Ideally, additional large randomized controlled trials are needed to properly  
298 assess this claim and whether vitamin D supplementation can significantly impact  
299 population risk.

300 This study has certain strengths and limitations. It included a large number of patients with  
301 heterogenous risk profiles in whom a variety of disease severity parameters were  
302 measured. In addition, a series of statistical tests were carried out to ensure minimal  
303 possibility of residual confounding. Nevertheless, some limitations must be acknowledged  
304 in order to properly interpret this study. First, a chemiluminescence immunoassay was  
305 used to assess vitamin D levels, this may lead to inconsistent results compared to other  
306 techniques including competitive binding protein - CBP, radioimmunoassay - RIA liquid  
307 chromatography - LC, UV detection with liquid chromatography and liquid chromatography  
308 mass spectrometry LCMS or tandem mass spectrometry. Since most patients were  
309 attended in the institution for the first time for COVID-19, historic vitamin D values were not  
310 available to assess the effect of vitamin D dynamics on infection risk or outcomes.  
311 Furthermore, given the disease course of COVID-19, severity profiles are highly  
312 heterogeneous even amongst hospitalized patients, which may influence vitamin D values  
313 on the basis of varying severity; control for this factor using propensity score matching was  
314 carried out, however, there remains a possibility for residual confounding. Notably, these  
315 results are from a COVID-19 reference center in Mexico City, this could reduce the  
316 representativeness of the findings. Further evidence in other regions of Mexico to confirm  
317 the role of vitamin D as a marker of disease severity and mortality in Mexicans with  
318 COVID-19 is needed.

## 319 **Conclusions**

320 Vitamin D levels lower or equal to 12 ng/ml (30nmol/L) are independently associated with  
321 COVID-19 mortality, even after adjusting for confounders (including measures of visceral  
322 and total body fat). No association was confirmed between vitamin D levels and the need  
323 for intubation. Vitamin D deficiency is more prevalent in women and patients with type 2  
324 diabetes mellitus. Vitamin D supplementation may be considered in deficient patients, but  
325 evidence of benefit is required from double blind randomized controlled trials.

327

328 **CONFLICT OF INTEREST/FINANCIAL DISCLOSURE:** Nothing to disclose.

329 **DATA AVAILABILITY:** Data is available from the corresponding author upon reasonable  
330 request. Code for reproducibility of results available at:  
331 [https://github.com/oyaxbell/covid\\_metabolism](https://github.com/oyaxbell/covid_metabolism)

332 **FUNDING:** This research did not receive any specific grant from funding agencies in the  
333 public, commercial, or not-for-profit sectors.

### 334 **ACKNOWLEDGMENTS**

335 All authors approved the submitted version. All the authors would like to thank the staff of  
336 the Endocrinology and Metabolism Department for all their support. We are thankful to the  
337 study volunteers for all their work and support throughout the realization of the study. AVV,  
338 and NEAV are enrolled in the PECEM program at the Faculty of Medicine of UNAM; AVV  
339 and NEAV are supported by CONACyT.

340 **CONTRIBUTIONS:** research idea and study design: RM, OYBC, CAAS; data acquisition:  
341 RM, PEVC, NRP, MAJA, CIPC, BRE, JCVG, CAAS; data analysis/interpretation: OYBC,  
342 RM, CAAS, NEAV, AVV; statistical analysis: OYBC, NEAV; manuscript drafting: RM,  
343 OYBC, NEAV, AVV, CAAS; supervision or mentorship: RM, CAAS, APL, JSO. Each  
344 author contributed important intellectual content during manuscript drafting or revision and  
345 accepts accountability for the overall work by ensuring that questions pertaining to the  
346 accuracy or integrity of any portion of the work are appropriately investigated and resolved.

510 **Supplementary Material**

511 **Table 1.** Clinical characteristics, imaging findings and severity scores in patients with COVID-19, comparing cases with and without  
 512 severely low vitamin D levels (vitamin D deficiency).

Parameter	Vitamin D [>12 ng/mL] (n=494)	Vitamin D [≤12 ng/mL] (n=57)	P-value
Age (years)	51.6 (13.7)	54.9 (13.9)	0.0865
Male Sex (%)	327 (66.2)	28 (49.2)	<b>0.01626</b>
Severe outcome (%)	142 (28.7)	24 (42.1)	0.0537
Intubation (%)	83 (16.8)	10 (17.4)	0.981
Letality (%)	95 (19.23)	21 (36.8)	0.0035
Low-Socioeconomic Status (%)	336 (68)	39 (68.3)	0.921
Arterial Hypertension (%)	150 (30.7)	22 (38.6)	0.293
Type 2 diabetes (%)	124 (25.5)	22 (38.6)	0.0512
Time since diagnosis (years)	9.1 (7.14)	11.6 (9.78)	0.297
Obesity (%)	204 (41.9)	25 (44.6)	0.8008
Smoking status (%)	26 (6.25)	1 (1.75)	0.921
CKD (%)	15 (3.10)	3 (5.26)	0.637
CVD (%)	14 (2.88)	2 (3.51)	0.921
Cirrhosis (%)	2 (0.41)	1 (1.75)	0.7256
BMI (kg/m <sup>2</sup> )	30.0 (5.29)	30.5 (8.76)	0.7227
Respiratory Rate (rpm)	28.4 (11.4)	28.7 (6.9)	0.7946

Heart Rate (bpm)	102.5 (18.3)	98.8 (18.3)	0.1545
Systolic Arterial Pressure (mmHg)	122 (110-132)	120 (110-136)	0.3157
Diastolic Arterial Pressure (mmHg)	75 (70-80)	73 (66-80)	0.242
Oxygen saturation (%)	81.7 (12.2)	78.8 (13.8)	0.1302
C-reactive protein	14.7 (7.8-21.9)	12.8 (6.7-27.9)	0.8042

513

514

Parameter	Vitamin D [>12 ng/mL] (n=494)	Vitamin D [≤12 ng/mL] (n=57)	P-value
Glucose levels (mg/dL)	152 (85.8)	185 (129.7)	0.0689
HbA1c (%)	6.3 (5.9-7.6)	8.0 (6.3-10.6)	0.00312
Triglycerides (mg/dL)	141 (111-183)	164 (118-237)	0.07487
HDL-C (mg/dL)	33 (13.4)	33 (7.78)	0.981
LDL-C (mg/dL)	84.7 (45.8)	80.3 (55.0)	0.887
Total Cholesterol (mg/dL)	147.7 (50.9)	135 (67.7)	0.7396
Hemoglobin	16.1 (12.3)	18.4 (28.9)	0.5584
