Abstract

Purpose: To corroborate whether vessels on the surface of the optic nerve head can provide protection against the loss of underlying axons in subjects with manifest glaucoma.

Methods: In this pilot study, thirty-six glaucomatous eyes with a perimetric defect in the Bjerrum area were included. The retinal nerve fiber layer (RNFL) thickness was measured in each of the sectors of the clock-hour map obtained by Cirrus HD-OCT considering the presence or absence of blood vessels. These sectors were related with their corresponding areas of the retina examined in the visual field using a mathematical model of the retina introduced by Jansonius, in order to determine the values of threshold sensitivity in those areas in the presence or absence of vessels.

Results: We corroborated the protective role of the blood vessel for peripapillary RNFL thickness of clock-hour 12 despite obtaining a p-value ($p = 0.023$; $w = 228.5$) close to the acceptance zone ($p \geq 0.05$). The mean ± standard deviation with vessel and without vessel were 70.95 ± 24.35 and 88.46 ± 23.96, respectively. No differences were found between the mean values of threshold sensitivity to the presence or absence of blood vessels in each of the sectors considered.

Conclusions: Our findings do not allow us to affirm that there is an association between the presence of a vessel and protection against glaucomatous damage in subjects with an

advanced manifestation of the disease. In the future, more extensive studies are needed to study this relationship in subjects with early glaucoma.

Key words: astrocytes, visual field, primary open-angle glaucoma, aqueous humor, blood vessel.

Introduction

Glaucoma is a multifactorial progressive optic neuropathy in which elevated intraocular pressure (IOP) is a strong risk factor [1]. The structural changes that occur during the development of the disease are well-defined [2], unlike its etiology, which still remains uncertain today.

The insufficient explanation of the pathogenesis of glaucoma by mechanical and vascular theory raises interest in the permeability of the optic nerve making way for a new hypothesis that name the existence of posterior aqueous humor flow could be a possible cause of glaucoma [3]. That explains and defines the structural changes that have occurred in the development of the disease to achieve its detection as early as possible, thanks to the incorporation and improvement of imaging diagnostic devices [4-7] without having to wait to the functional manifestations of the visual field, in which case the loss of nerve fibers is irreversible and of great amount [8].

There is a fourth posterior pathway through which part of the aqueous humor leaves the eye, through the vitreous and the retina, without entering the anterior chamber. This is due to the lack of an epithelial barrier on the anterior surface of the vitreous. When there is an increase in resistance in the regulation of the aqueous humor outflow normal pathway with an increase in IOP, these discontinuities or holes produce an increase in aqueous humor flow toward the posterior pole [9]. This process is supported by the existence of optic nerve head (ONH) permeability, since the nerve`s vitreous interface is

formed by astrocytes, where fenestrations are described that allow the free passage of fluid and solutes from the vitreous to prelaminar tissue [10, 11]. These astrocytes are united to each other and to the extracellular matrix, among others, by adherent junctions rich in N-cadherine, a calcium dependent adhesion molecule. These types of unions are characterized by allowing the passage of water and small molecules, which confer a permeability to the ONH [9]. When the aqueous humor, poor in calcium, passes through the optic nerve and comes into contact with astrocytes, it produces a separation of the adherent junctions due to a drop in calcium concentrations in these junctions. This would produce a rupture of the membrane junctions between the astrocytes and cause their destruction, allowing the introduction of the aqueous humor into the extracellular spaces of the optic nerve [11,12]. Do not forget that astrocytes are considered as essential elements for protecting axons of the optic nerve [3].

This new hypothesis, which is defended in the present study, should explain the loss of axons in conditions of high or low IOP and account for the initial or early damage of glaucoma in the ONH as a consequence of the deviation of the aqueous humor outlet during the development of glaucoma toward the posterior pole, in which there is protective role played by the blood vessel covering the underlying axons [3, 9].

This new postulate would allow determining the pattern of visual field loss because the scotomas would be limited in their extent by the projection of the blood vessels in the visual field [9,11,12]. Being possible to carry out a detection as early as possible, through the techniques of perimetric and morphological data, to adopt the appropriate therapeutic measures.

There are mathematical models that can be used to predict the location and progression of scotomas in glaucoma. We propose to use the Jansonius model [13,14], based on photographic images of the retina, to relate structural and functional injury. The area of

92 the papilla covered by the central vessels of the retina corresponded to the delimited
93 papillary border by dividing the optic nerve into sectors generated by OCT. While the
94 Jansonius algorithm determines the area of the retina where the dendritic trees of the
95 ganglion cells are located.
96 The objective of the present study is to confirm, in patients affected by glaucomatous
97 visual field damage, whether the presence of a blood vessel on the surface of the ONH
98 provides protection against the progressive destruction of underlying axons.
99

100 **Methods**

101 **Study participants**

102 This was a cross-sectional study. All subjects were recruited from the hypertension
103 consultation at the Vista-Ircovisión ophthalmological center, in Murcia between May
104 2018 and September 2018.
105 All subjects underwent a full ophthalmic examination: a review of clinical history, best-
106 corrected visual acuity, slit-lamp biomicroscopy, intraocular pressure measurement by
107 applanation tonometry, automated perimetric- visual field assessment with Octopus 600
108 (Bloss, software version 3.6.1. Haag-Streit, Switzerland) and peripapillary analysis using
109 optical coherence tomography (OCT) with Cirrus HD-OCT (Carl Zeiss Meditec, Inc.,
110 Dublin, CA; software version: 6.0.2.81) based on spectral domain (SD) technology using
111 the Optic Disc Cube 200x200 protocol.
112 The inclusion criteria for both normal subjects and glaucoma patients were age > 18 years
113 old, no history of retinal disease or optic nerve disease including non-glaucomatous optic
114 neuropathy, ocular surgery, diabetes mellitus, hypertension and refractive error < 5
115 diopters of sphere or 3 diopters of cylinder. Glaucoma subjects were included if they had
116 a definitive diagnosis of visual field damage in the Bjerrum area.

Study protocol

The ONH parameters that were analyzed were RNFL thickness of all 12 clock-hour sectors listing them clockwise in the right eye and counterclockwise in the left eye. The presence or absence of a blood vessel, in each of the sectors studied in the peripapillary region, was done by superimposing the clock-hour map on the fundus photograph obtained with OCT (Fig. 1).

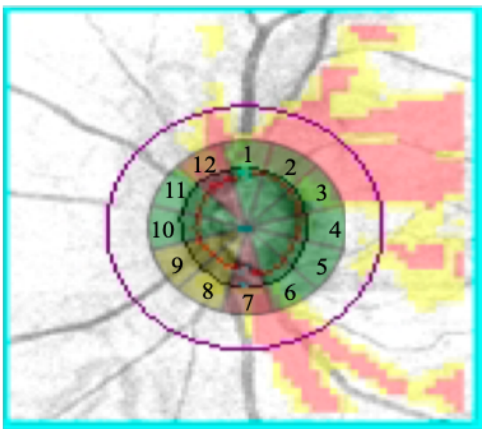

Figure 1. Superimposition of the clock-hour map onto the fundus photography of the optic nerve with Cirrus-HD. We observe the presence of blood vessels at clock-hour 1, 7, 8, 9 and 11 in a patient diagnosed with glaucoma.

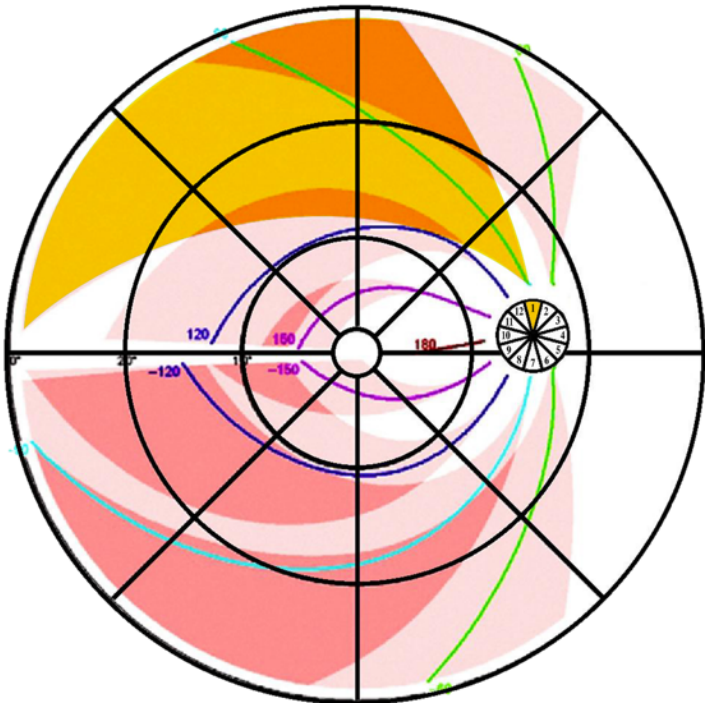
In order to obtain threshold sensitivity values, the mathematical retinal model of Jansonius (2009) [13] was used to connect the bundle of nerve fibers of a certain region of the retina examined by the visual field with the corresponding area of input of that bundle of fibers in the peripapillary region of the optic nerve. Jansonius (2009) [13] introduced a mathematical model for describing the nerve fiber bundle trajectories of the human retina. To do this, we adapted the clock-hour map within the determined position of the optic nerve in the Jansonius model (2009) [13] matching each fiber bundle with each of the 12 sectors of the clock-hour map, thus obtaining our own proposed model to relate the structural and functional damage (Fig. 2). The threshold sensitivity value per

137 sector was obtained by projecting each bundle of Jansonius nerve fibers onto the visual
138 field examination considering the inversion that needed to be made (the nasal hemiretina
139 was evaluated by the temporal visual field, the temporal hemiretina was evaluated by the
140 nasal visual field, the superior hemiretina was evaluated by the inferior visual field and
141 the inferior hemiretina was evaluated by the superior visual field).



142

143 **Figure 2**. Adaptation of the clock-hour map to the mathematical retina model of
144 Jansonius (2009). It is observed how each nerve fiber bundle trajectory in the human
145 retina matches to the corresponding individual clock-hour sector of the ONH (the whole
146 12 clock-hours). An example is shown of the correspondence made in the right eye
147 between the trajectory of the bundle axons along the retina according to Jansonius
148 (indicated in yellow) and its corresponding input region (clock-hour 1 in yellow) in the
149 ONH.

150

151 We calculated the mean RNFL thickness values and threshold sensitivity by stratifying
152 each of the sectors into two groups, in order to subsequently compare the glaucomatous

153 group with the presence of the blood vessel versus the glaucomatous group with absence
154 of the blood vessel in the analysis of the protective role of vessels in glaucomatous
155 damage. Similarly, previously, we measured the average values of RNFL thickness and
156 threshold sensitivity by sectors in the recruited group of control subjects to verify the
157 validation of our own proposed model. For this study, clock-hours 3, 4 and 5 were not
158 included in the statistical analysis of the variables due to the limited data obtained from
159 this area because it corresponds to the nasal side of the retina and is not affected by
160 glaucomatous injury.

161 **OCT Scanning**

162 Peripapillary ONH parameters were measured in each participant by optical coherence
163 tomography. Optic Disc Cube 200x200 protocol of Cirrus HD-OCT was used for scan
164 acquisition of the optical disc head. The protocol generates a cube of data over a 6x6 mm2
165 area centered on the optic disc by acquiring a series of 200 A-scans from 200 linear B-
166 scans (40,000 points) in about 1.5 seconds (27,000 A-scans/sec). For analysis, a built-in
167 automated algorithm identifies the center of the optic disc and places a circle of 3.46 mm
168 diameter evenly around it. After automated RNFL segmentation, the system takes
169 samples from the data cube of 256 A-scans along the path of the scan circle to obtain
170 average and sectorial (12 clock-hours) RNFL thickness. While centering and performing
171 the Cirrus-HD OCT test, patient monitoring is possible. Only good quality scans were
172 used for analysis, defined as having a signal strength greater or equal to 6 (10 =
173 maximum) without discontinuity or misalignment, involuntary saccade or blinking
174 artifacts. The parameters used for the analysis of the optic nerve head were the clock-hour
175 map and mean nerve fiber layer (NFL) thickness.

176

Visual Field Testing

All participants underwent the G-Program of the Octopus perimeter, TOP strategy, 30 central degrees, white-on-white perimetry, stimulus size III, time of exposure 100ms using standard background lighting of 4 apostilbs. The visual fields were classified as reliable if the reliability factor, RF, was <15%.

Glaucomatous visual field damage was defined based on at least 3 or more contiguous depressive test points within the typical glaucoma location (Bjerrum area) with a pattern deviation plot at p<5% or a corrected standard deviation occurring in less than 5% of the normal field.

Statistical analysis

To compare the means in the different groups, the Wilcoxon-Mann-Whitney test was used. R Studio version 1.1.423 was used for statistical analysis in order to have a simple way to execute the sentences of the programming language R version 3.5.0 (2018-04-23) necessary to obtain the desired analyses. In all analyses, p-values < 0.05 were considered significant.

Results

The following participants were recruited: 27 control subjects (36 eyes) and 29 patients (36 eyes) diagnosed with primary open-angle glaucoma (POAG). In all, 72 patients aged 50-79 years were included. The patients of the study group had been diagnosed by a glaucoma specialist and were in follow-up for the disease, after having undergone the functional test with at least 5 visual fields prior to their recruitment. Even so, 9 patients were eliminated because the reliability limits established in the perimeter used were

exceeded (RF <15%). All patients had glaucomatous visual field defects (Bjerrum area) and glaucoma was classified as advanced if the average value of MD = 10.25 ± 4.98 (>/= 6dB). The normal control subjects presented normal perimetries and no evidence of structural or functional glaucomatous damage (Table 1).

Table 1. Baseline characteristics of the normal control and glaucoma patients.

	Mean age (years)	MD (dB)	sLV (dB)	RFNL Average thickness (µm)
Normal	58.5 ± 6.6	-0.25 ± 1.03	1.77 ± 0.41	90.9 ± 5.4
Glaucoma	67.9 ± 9.4	10.25 ± 4.98	6.71 ± 1.85	63.7 ± 8.6

MD = mean defect; sLV = square loss variance; RFNL = retinal fiber layer.
Data are expressed as the mean ± SD.

Regarding our work methodology, we found our regions of the visual field with their corresponding sections of analysis of nerve fibers of the ONH of the hour circle by OCT, when comparing our model with that used in the only study found among the bibliography that performs a topographical correspondence between functional and structural tests [15]. No other Jansonius-based model was found. Likewise, we found analogous with other studies the mean values of nerve fiber thickness in each of the sections considered (Table 2), [5,16] as well as the value of the mean visual field defect [17] both in the group of subjects. control as glaucomatous patients.

Table 2. Peripapillary Retinal Nerve Fiber Layer Thickness (μm) of normal control and glaucoma patients by location for Cirrus HD-OCT.

Parameter	Normal	Glaucoma
Sector 1	111.91 ± 22.22	72.72 ± 19.90
Sector 2	102.33 ± 13.00	74.11 ± 18.82
Sector 6	93.77 ± 16.09	66.88 ± 14.93
Sector 7	125.69 ± 17.34	73.80 ± 18.94
Sector 8	131.58 ± 16.84	68.41 ± 19.16
Sector 9	63.38 ± 9.45	47.27 ± 11.64
Sector 10	49.16 ± 5.16	47.36 ± 12.07
Sector 11	73.86 ± 9.97	58.00 ± 16.07
Sector 12	126.05 ± 15.05	78.25 ± 25.40

Data are expressed as the mean ± SD

We can affirm that our data obtained from our analyzed sample are correct when finding common analogous findings with respect to other studies. This, together with the previous knowledge we have of the disease, allows us to accept as valid our proposed model to match the regions of the visual field with their corresponding sectors of the optic nerve.

Therefore, we start from the creation of a correct model that allows us to study / analyze the main objective of this work, which is to corroborate if the blood vessel really has a protective role against glaucomatous lesion. We found that its influence was only confirmed in section 12 of the examination of the hourly circle for the thickness of NFL after the application of the WMW test, after checking the non-normality of the variables involved using the Shapiro-Wilk test, confirming the rejection of equality of means (μ1

231 = μ2) despite the fact that the obtained value was very close to the acceptance zone ($p \geq$
232 0.05), considering therefore the test that for this section the vessel does influence the
233 thickness of NFL in glaucomatous subjects (Table 3).

234

Table 3. Comparison of results of mean sensitivity (dB) and peripapillary RNFL (μm) of glaucoma patients by location with vessel/without vessel.

	Glaucoma (dB)		Glaucoma (μm)	
	with vessel	without vessel	with vessel	without vessel
Sector 1	14.90 ± 7.33	15.98 ± 7.17	73.63 ± 19.82	68.16 ± 21.57

239

Discussion

The application of an early diagnosis of glaucoma and early intervention treatment plan, without having to wait for clearly defined visual field losses, has led to the emergence of a variety of types of new diagnostic imaging technology with the objective of measuring structural changes which is very useful in glaucoma treatment [4-7].

In spite of all the studies that have attempted to confirm that the new imaging techniques are good predictors of early structural glaucomatous damage, others question the ability of these techniques [18–21].

There is no unanimous consensus on whether structural damage precedes functional progression in glaucomatous eyes [22, 23]. It is probably caused by a definition problem due to the limitation of instrumental capacity, specificity and sensitivity [24]. In addition, we must not forget that we define and understand the term "early diagnosis" as the presence of early signs of glaucoma, which in turn are characterized by being highly variable and difficult to catalog [25]. In the clinical setting, we often find patients with evidence of glaucomatous optic neuropathy without a detectable visual field abnormality, patients with a glaucomatous visual field without detectable structural abnormality and patients with a similar degree of stages of glaucomatous structural alterations but with different levels of losses in the field visual [22]. Therefore, the diagnosis and monitoring of glaucoma cannot be made based on a single examination.

We believe, like other researchers, that the problem really lies in the difficulty of the concordance and relationship between the perception of the differential threshold obtained by the visual field and the reduction of ganglion cells detected by the OCT [26]. The problem with all this lies in the fact that there is no linear relationship between the measurements used in each test. The visual field uses logarithmic units of measurement, decibels (dB), measuring the differential light sensitivity of the subject which are related

265 to the luminance of the stimulus relative to the background. Therefore, it does not express
266 the value of the detected luminosity as an absolute value but as a relative value. In
267 addition, OCT measures the thickness of peripapillary RNFL in linear units (μm) giving
268 a reference value with respect to normality measurements, as the μm is a linear unit which
269 has a direct measurement relationship with retinal ganglion cell density [22, 24].
270 It has been tried, without success, to create a model that relates both tests. Several authors
271 have attempted to do this, and even here there is still a diversity of opinions. Some believe
272 it is better to generate models whose association is considered more correct if both tests
273 are transferred to linear units [27] and others believe that, on the contrary, the association
274 is better if it is done in logarithmic units [29].
275 A possible solution and contribution, particularly for the improvement of lineal models,
276 is the model we propose in our study. We suggest determining a map in order to make up
277 for the lack of knowledge, which determines a relationship between structure and
278 functional damage in glaucoma, to match a bundle of nerve fibers of a certain region of
279 the retina examined by the visual field with the corresponding area of input of that bundle
280 of fibers in its corresponding sector in the ONH. In this way, we could obtain the thickness
281 of peripapillary nerve fibers measured by the OCT and the sensitivity values measured
282 by the visual field corresponding to each clock-hour sector. The best-considered and
283 most-used model for this is the Galway Heath (2000) [28] on which the Jansonius
284 retinotopic model (2009) [13] is based, and which we have used to generate our own
285 model. It differs from the rest by making a mathematical model mapping nerve fiber
286 bundle trayectories in the retina, describing a clear asymmetry between the superior and
287 inferior hemifields and providing a detailed location-specific estimate of the magnitude
288 of variability [14].
289

According to our data (Table 2), we can affirm that our model, which relates structural to functional function, is reliable in trying to respond to the objective of this study since all efforts are directed towards early detection of the disease in order to thus approaching it with the most appropriate therapeutic considerations [25]. Reflection that leads us to ask ourselves how to know that therapeutic action to apply is the correct one if the etiopathogenesis of glaucoma is not really known. To resolve this question, after initially programming our work methodology, we decided to clinically check one of the postulates that this new theory defends [30,31]: if the blood vessel really has a protective role against glaucomatous lesion both at the level of fiber thickness nerve as in light sensitivity values in each of the 9 sections considered in the groups formed (group of subjects with glaucoma in whose sections there is a presence of a vessel versus group of subjects with glaucoma in whose sections there is no presence of a vessel) (Table 3). Note that the sections in which we are going to find the position of a vessel will be section 1 and 7, followed by section 2 and 6, respectively corresponding to the limiting region of the fibers of the Bjerrum area and immediately more peripheral to these . In contrast, the sections belonging to the papillo-macular bundle (sections 9, 10 and 11) are the most numerous in the absence of a blood vessel.

Conclusion

In conclusion, we only found the protective role of a blood vessel was strongest for clock-hour 12 on the thickness RFNL. We did not find an influence of the protective role of a blood vessel for sensitivity values in any individual sector of the clock-hour map studied. We cannot confirm that the blood vessel has a protective role against glaucomatous damage based on the data obtained and we are not able to compare our results with those obtained by other authors. To our knowledge, this is the first study that clinically proves

315 the protective role hypothesis of the blood vessel in glaucomatous damage and it supports
316 new theories that may determine the pathogenesis of glaucoma.
317 Based on these findings, additional studies are needed to evaluate the protective role of
318 the blood vessel applied to subjects with early glaucomatous damage, to check whether
319 there is a greater advance in the disease comparing those sectors with or without vascular
320 protection. It would also be interesting to study functionality by microperimetry which
321 has the capacity to detect minimum variations of the visual threshold in a more precise
322 way than the visual field.

STROBE Statement—Checklist of items that should be included in reports of ***cross-sectional studies***

	Item No	Recommendation
Title and abstract	1	(*a*) Indicate the study's design with a commonly used term in the title or the abstract: *"Title, page 2"*
		(*b*) Provide in the abstract an informative and balanced summary of what was done and what was found: *"Abstract, paragraph 2,3"*
Introduction		
Background/rationale	2	Explain the scientific background and rationale for the investigation being reported: *"Background, paragraph 2,3,"*
Objectives	3	State specific objectives, including any prespecified hypotheses: *"Background, Paragraph 4,5"*
Methods		
Study design	4	Present key elements of study design early in the paper: *"Methods, paragraph 1"*
Setting	5	Describe the setting, locations, and relevant dates, including periods of recruitment, exposure, follow-up, and data collection: *"Methods, paragraph 1"*
Participants	6	(*a*) Give the eligibility criteria, and the sources and methods of selection of participants: *"Methods, paragraph 3"*
Variables	7	Clearly define all outcomes, exposures, predictors, potential confounders, and effect modifiers. Give diagnostic criteria, if applicable
Data sources/ measurement	8*	For each variable of interest, give sources of data and details of methods of assessment (measurement). Describe comparability of assessment methods if there is more than one group
Bias	9	Describe any efforts to address potential sources of bias: *"N/A"*
Study size	10	Explain how the study size was arrived at: *"N/A"*
Quantitative variables	11	Explain how quantitative variables were handled in the analyses. If applicable, describe which groupings were chosen and why: *"N/A"*
Statistical methods	12	(*a*) Describe all statistical methods, including those used to control for confounding
		(*b*) Describe any methods used to examine subgroups and interactions: *"N/A"*
		(*c*) Explain how missing data were addressed: *"N/A"*
		(*d*) If applicable, describe analytical methods taking account of sampling strategy: *"N/A"*
		(*e*) Describe any sensitivity analyses: *"N/A"*
Results		
Participants	13*	(a) Report numbers of individuals at each stage of study—eg numbers potentially eligible, examined for eligibility, confirmed

		eligible, included in the study, completing follow-up, and analysed: *"Results, paragraph 1"*
		(b) Give reasons for non-participation at each stage: *"Results, paragraph 1"*
		(c) Consider use of a flow diagram: *"N/A"*
Descriptive data	14*	(a) Give characteristics of study participants (eg demographic, clinical, social) and information on exposures and potential confounders: *"N/A"*
		(b) Indicate number of participants with missing data for each variable of interest: *"N/A"*
Outcome data	15*	Report numbers of outcome events or summary measures: *"Results, paragraph 1"*
Main results	16	(*a*) Give unadjusted estimates and, if applicable, confounder-adjusted estimates and their precision (eg, 95% confidence interval). Make clear which confounders were adjusted for and why they were included: *"N/A"*
		(*b*) Report category boundaries when continuous variables were categorized: *"N/A"*
		(*c*) If relevant, consider translating estimates of relative risk into absolute risk for a meaningful time period: *"N/A"*
Other analyses	17	Report other analyses done—eg analyses of subgroups and interactions, and sensitivity analyses: *"N/A"*
Discussion		
Key results	18	Summarise key results with reference to study objectives: *"Conclusion,paragraph 1"*
Limitations	19	Discuss limitations of the study, taking into account sources of potential bias or imprecision. Discuss both direction and magnitude of any potential bias: *"Conclusion,paragraph 2"*
Interpretation	20	Give a cautious overall interpretation of results considering objectives, limitations, multiplicity of analyses, results from similar studies, and other relevant evidence: *"Conclusion,paragraph 1"*
Generalisability	21	Discuss the generalisability (external validity) of the study results. *"Conclusion,paragraph 1"*
Other information		
Funding	22	Give the source of funding and the role of the funders for the present study and, if applicable, for the original study on which the present article is based: *"N/A"*
