## **ABSTRACT**

### **Background**

Some patients experience long-term symptoms after COVID-19, but data on outpatients with mild-to-moderate COVID-19 are scarce.

### **Objective**

To describe persisting symptoms more than 3 months after infection in PCR-confirmed COVID-19 in comparison to negative SARS-CoV-2 PCR outpatients and to identify predictors of long-term symptoms in COVID-19.

### **Setting**

Outpatient clinics of a Swiss university center.

### **Patients**

418 symptomatic outpatients with PCR-confirmed COVID-19 (COVID-positive) and 89 negative SARS-CoV-2 PCR (COVID-negative).

### **Design**

Prospective cohort study.

### **Measurements**

Predefined long-term symptoms were evaluated through a phone interview >3 to 10 months after diagnosis.

Associations between long-term symptoms and PCR test result, as well predictors of persisting symptoms in COVID-positive were evaluated by multivariate logistic regression including potential confounders (age, sex, smoking, comorbidities, time of the phone survey).

### **Results**

The study population consisted mostly of young (median of 41 versus 36 years in COVID-positive and COVID-negative, respectively;  $p=0.020$ ) health care workers (67% versus 82%;

$p=0.006$ .. Persisting symptoms were reported by 223 (53%) COVID-positive and 33 (37%) COVID-negative ( $p=0.006$ ). Overall, 21% COVID-positive and 15% COVID-negative ( $p=0.182$ ) consulted a doctor for these symptoms. Four surveyed symptoms were independently associated with COVID-19: fatigue (adjusted odds ratio [aOR] 2.14, 95%CI 1.04-4.41), smell/taste disorder (26.5, 3.46-202), dyspnea (2.81, 1.10-7.16) and memory impairment (5.71, 1.53-21.3). Among COVID-positive, female gender (aOR 1.67, 95% CI 1.09-2.56) and overweight/obesity (1.67, 1.10-2.56) were predictors of persisting symptoms.

### **Limitations**

Undiagnosed SARS-CoV-2 infection in COVID-negative cannot be completely excluded.

### **Conclusion**

More than half of COVID-positive outpatients report persisting symptoms up to 10 months after infection and 21% seek medical care for this reason. These data suggest that post-COVID syndrome places a significant burden on society and especially healthcare systems.

## 1 INTRODUCTION

2 More than one year after the first cases of Coronavirus disease 2019 (COVID-19) (1), the  
3 severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) pandemic remains a constant  
4 threat challenging the capacity of healthcare systems and affecting well-being of many  
5 individuals. The clinical presentation and outcome of acute COVID-19 is well described, most  
6 patients presenting with mild disease and only a minority needing hospital admission (2).  
7 While most affected people experience complete resolution of their symptoms after two to  
8 six weeks (3,4), symptoms lasting more than 3 months have been reported in social media (5–  
9 7) and in observational studies (8–13). Three studies reported that a large number of patients  
10 have persisting symptoms for more than 6 months after COVID-19: one study including adults  
11 discharged from hospital (14) and two studies including outpatients with mild-to-moderate  
12 disease (15,16). Recent guidelines defined post-COVID-19 syndrome as the persistence of  
13 signs and symptoms for more than 3 months after infection in the absence of an alternative  
14 diagnosis (17).

15 Although they represent the vast majority of cases, data on long-term consequences in  
16 outpatients with mild-to-moderate COVID-19 are still scarce. To the best of our knowledge,  
17 no study compared the prevalence of persisting symptoms among patients screened for  
18 similar symptoms, between those tested positive for SARS-CoV-2 and those tested negative.  
19 Therefore, the association between PCR-confirmed COVID-19 and long-term symptoms is not  
20 well established. Furthermore, no study explored the factors associated with persisting  
21 symptoms in outpatients. These data are crucial as they may modify patients' follow-up after  
22 their infection and influence public health vaccination strategies by identifying additional  
23 population groups that should be prioritized.

24 We aimed to compare the prevalence of symptoms persisting for more than 3 months  
25 between SARS-CoV-2 PCR-confirmed (COVID-positive) and PCR-negative (COVID-negative)  
26 patients in outpatient clinics, and to identify predictors of persisting symptoms in COVID-  
27 positive.

28

## 29 **METHODS**

### 30 **Study design, setting and participants**

31 This cohort study recruited consecutive PCR-confirmed COVID-19 patients (COVID-positive  
32 group) during their initial visit in the emergency department (ED) or in the SARS-CoV-2  
33 screening center of the University hospital of Lausanne, as well as in the two outpatient clinics  
34 of the University of Lausanne, Switzerland, between February 26<sup>th</sup> and April 27<sup>th</sup> 2020. During  
35 the study period, SARS-CoV-2 screening was restricted to symptomatic patients (i.e.  
36 symptoms of acute respiratory tract infection, anamnestic fever or sudden loss of smell or  
37 taste) with at least one risk factor for severe COVID-19 (i.e.  $\geq$  65 years old or presence of a  
38 comorbidity such as hypertension, diabetes, cancer, chronic cardiac or respiratory disease,  
39 immunosuppression) and to symptomatic health workers (18). Validated nucleic acid  
40 amplification tests were used and a dedicated trained medical team performed the  
41 nasopharyngeal swabs (19).

42 We included a control group of outpatients attending the same health facilities during the  
43 same period with symptoms suggestive of COVID-19 (cough and/or dyspnea) at presentation,  
44 but a negative PCR SARS-CoV-2 result in nasopharyngeal swab (COVID-negative group). This  
45 group was part of a prospective cohort of patients with acute respiratory infections previously  
46 described (20,21).

47 We excluded patients who 1) did not have a documented health assessment at the time of  
48 the test, 2) were hospitalized (for more than 24 hours) on the day of initial visit or within the  
49 following 30 days, 3) were unable to understand the phone survey due to a language barrier  
50 or a cognitive impairment, 4) declined to participate, 5) were not reachable for the phone  
51 interview after at least two attempts or 6) had the phone survey less than 3 months after the  
52 initial visit. Patients who had a positive SARS-CoV-2 test performed in another location before  
53 the initial visit in the study centers were excluded, as we also planned to evaluate the impact  
54 of the infection on healthcare system (i.e. medical consultations for persisting symptoms).  
55 Moreover, we excluded COVID-negative patients who declared having a documented (PCR or  
56 serology) SARS-CoV-2 infection after the initial consultation up to the phone follow-up.

#### 57 **Procedures**

58 We retrospectively extracted data from the patients' electronic medical records:  
59 demographics, medical history, initial clinical presentation, and SARS-CoV-2 real-time reverse  
60 transcriptase PCR (RT-PCR) cycle thresholds. We prospectively conducted a structured and  
61 standardized phone survey more than 3 three months after SARS-CoV-2 diagnosis to collect  
62 information on (1) persisting symptoms at the time of the call, (2) secondary hospital  
63 admission within 30 days of the initial consultation, (3) medical consultation for persisting  
64 symptoms until the call, and (4) anthropometric data. The survey included 14 pre-defined  
65 symptoms: fatigue, muscle weakness, dyspnea, cough, thoracic pain, smell or taste disorder,  
66 blurred vision, headache, memory impairment, loss of balance, numbness, nausea, sleep  
67 disorder, and hair loss. Dyspnea was further categorized according to New York Heart  
68 Association (NYHA) grades (22). The calls were performed by physicians of the infectious  
69 diseases service of the University Hospital of Lausanne.

70 All data were entered in the Lausanne University Hospital's electronic database "regCOVID"  
71 using the REDCap® platform (Research Electronic Data Capture v8.5.24, Vanderbilt University,  
72 Tennessee, USA) (20,23).

### 73 **Definitions**

74 Long-term symptoms were defined as symptoms that appeared during the acute infection  
75 phase, were still present at time of the phone call (i.e. >3 months after the initial consultation)  
76 and were not explained by an alternative diagnosis. Smell or taste disorder included partial or  
77 complete loss of that sense. Numbness included hypoesthesia and paresthesia.

78 To account for the timing of symptoms assessment, we classified COVID-positive patients in  
79 three equivalent periods according to the time between SARS-CoV-2 diagnosis (initial  
80 consultation) and the phone interview: first period: >3 months to 5 months after diagnosis,  
81 second period: >5 months to 7 months after diagnosis, and third period: >7 months to 10  
82 months after diagnosis.

### 83 **Statistical analyses**

84 Demographics, clinical features at the time of initial consultation, consultation for persisting  
85 symptoms and prevalence of long-term symptoms (any symptom or individualized symptoms)  
86 were compared between COVID-positive and COVID-negative by Mann Whitney-U, *chi*-  
87 squared, or Fisher tests as appropriate, as well as between COVID-positive patients surveyed  
88 during the three different periods after SARS-CoV-2 diagnosis by 1-way ANOVA, Kruskal-Wallis  
89 or chi-squared as appropriate. A *p* value <0.05 was considered statistically significant. The  
90 association between COVID-19 and long-term symptoms was evaluated by multivariate  
91 logistic regression including potential confounders (age, sex, smoking, comorbidities, period  
92 of the phone survey). The independent association between the previously mentioned factors

93 and long-term symptoms in COVID-positive was evaluated by multivariate logistic regression  
94 including the same potential confounders.

95 STATA (version 15.1, Stata Corp, College Station, TX, USA) statistical software and GraphPad  
96 Prism 8.3 (GraphPad, San Diego, CA, USA) were used for analyses.

## 97 **Ethics**

98 The project was approved by the Ethics Committee of the Canton of Vaud, Switzerland. All  
99 participants gave their verbal consent to participate in this study during the phone interview  
100 (project-ID CER-VD 2020-01107 and 2019-02283).

101

## 102 **RESULTS**

103 A total of 956 symptomatic patients had a RT-PCR-confirmed COVID-19 between February 26<sup>th</sup>  
104 and April 27<sup>th</sup>, 2020. We excluded 198 patients who were admitted within 30 days of the initial  
105 visit (151 on the day of the first visit and 47 in the following 30 days) and 340 with other  
106 exclusion criteria described in Figure 1. The remaining 418 (44%) COVID-positive patients were  
107 included in the analysis. We contacted 131 COVID-negative patients who consulted with  
108 symptoms suggestive of COVID-19 and had a negative SARS-CoV-2 RT-PCR between March  
109 31<sup>st</sup> and April 26<sup>th</sup>, 2020. We excluded 19 patients who had a positive SARS-CoV-2 test (RT-  
110 PCR or serology) between the time of the initial visit and the time of the phone survey, 17 who  
111 could not be reached, 3 who refused to participate, 2 who did not speak one of the  
112 investigators' languages and one who died. The remaining 89 (68%) COVID-negative patients  
113 were included in the analysis.

### 114 ***Demographics and clinical presentation***

115 In both groups, there was a majority of women and health care workers. Approximately a third  
116 of patients suffered from a comorbidity, mainly obesity, arterial hypertension, and asthma

117 (Table 1). Most patients were tested within the first week of symptom onset and had normal  
118 vital signs at initial consultation. Compared to COVID-negative, COVID-positive were slightly  
119 older and less often health care workers, active smokers, and asthmatic. COVID-positive  
120 reported less often a history of fever, dyspnea, or sore throat at the time of evaluation.

121 The study team assessed long-term symptoms via the phone survey at a median of 105 days  
122 (interquartile range [IQR], 121-204 days) and 242 days (IQR 236-248 days) after the initial  
123 consultation in the COVID-positive and COVID-negative groups, respectively ( $p<0.001$ ). The  
124 study team called 190 (45%) COVID-positive during the first period (>3 to 5 months after the  
125 initial visit), 102 (24%) during the second period (>5 to 7 months) and 126 (30%) during the  
126 third period (>7 to 10 months). Patients surveyed in the first period were significantly older,  
127 less often health-care workers and had more comorbidities than those in the two other  
128 periods (Appendix Table 1). The study team called all COVID-negative during the third period.

### 129 ***Long-term symptoms***

130 At the time of the phone survey, 223/418 (53%) COVID-positive and 33/89 (37%) COVID-  
131 negative patients ( $p=0.006$ ) reported the presence of any long-term symptom (Figure 1A,  
132 Table 2).

133 In COVID-positive, the main reported symptoms were fatigue ( $n=132$ , 32%), smell or taste  
134 disorder ( $n=93$ , 22%), dyspnea ( $n=66$ , 16%), headache ( $n=50$ , 12%), memory impairment  
135 ( $n=48$ , 11%), hair loss ( $n=43$ , 10%), and sleep disorder ( $n=41$ , 10%). The prevalence of long-  
136 term symptoms was similar during the 3 periods surveyed (Figure 2B). In COVID-negative, the  
137 main reported symptoms were fatigue ( $n=15$ , 17%), headache ( $n=10$ , 11%), sleep disorder  
138 ( $n=10$ , 11%), and dyspnea ( $n=7$ , 8%).

139 COVID-positive reported more often smell or taste disorder ( $p=0.001$ ), fatigue ( $p=0.006$ ) and  
140 memory impairment ( $p=0.003$ ) than COVID-negative. The prevalence of other symptoms was

141 similar between COVID-positive and COVID-negative. The proportions of patients with  $\geq 2$  and  
142  $\geq 3$  symptoms were greater in COVID-positive than COVID-negative (38% vs 19%;  $p=0.001$  and  
143 23% vs 9.0 %;  $p=0.002$ , respectively). The proportion of patients requiring a medical  
144 consultation for persisting symptoms was similar between COVID-positive and COVID-  
145 negative (21% versus 15%,  $p=0.182$ ).

#### 146 ***Independent association between COVID-positive status and long-term symptoms***

147 After adjusting for potential confounders, COVID-positive status was a predictor for reporting  
148 any symptom (adjusted odds ratio [aOR] 2.04, 95% CI 1.14-3.67;  $p=0.02$ ), fatigue (aOR 2.14,  
149 95% CI 1.04-4.41;  $p=0.04$ ), dyspnea (aOR 2.81, 95% CI 1.10-7.16;  $p=0.03$ ), smell or taste  
150 disorder (aOR 26.5, 95% CI 3.46-202;  $p<0.01$ ) and memory impairment (aOR 5.71, 95% CI 1.53-  
151 21.3;  $p=0.01$ ) at the time of the phone survey (Table 2). Of note, dyspnea associated with  
152 limited physical activity (NYHA  $\geq 2$ ), as well as other long-term symptoms were not associated  
153 with COVID status.

#### 154 ***Predictors of long-term symptoms in COVID-positive***

155 While 57% of women presented long-term symptoms, only 47% of men did ( $p=0.049$ ). While  
156 59% of overweight/obese patients presented long-term symptoms, only 49% of patients with  
157 healthy weight did ( $p=0.041$ ). After adjusting for potential confounders, independent  
158 predictors of reporting any long-term symptoms were still female gender (aOR 1.67, 95% CI  
159 1.09-2.56;  $p=0.019$ ) and overweight/obesity (aOR 1.67, 95% CI 1.10-2.56;  $p=0.017$ ; Table 3).  
160 The same predictors were associated with long-term fatigue. Predictor of dyspnea was  
161 overweight/obesity. Predictor of smell or taste disorder was female gender. Predictor of  
162 memory impairment was active smoking (Figure 3). Predictors of other long-term symptoms,  
163 which were not associated with COVID status, are presented in Appendix table 2.

164

165 **DISCUSSION**

166 In a large cohort of PCR-confirmed COVID-19 outpatients, we evaluated the prevalence of  
167 persisting symptoms 3 to 10 months after diagnosis and compared it with a cohort of negative  
168 SARS-CoV-2 PCR patients included during the same period with a similar clinical presentation.  
169 In these study populations consisting mostly of young and healthy participants, most working  
170 as health care workers, we showed that 53% of patients with PCR-confirmed COVID-19 report  
171 persisting symptoms, while 37% with negative SARS-CoV-2 PCR do. Interestingly, only 4 out of  
172 the 14 surveyed persisting symptoms were independently associated with COVID status, i.e.  
173 fatigue, smell or taste disorder, dyspnea and memory impairment.

174 The type and prevalence of long-lasting symptoms in COVID-positive are consistent with  
175 existing literature. In a systematic review and meta-analysis of studies evaluating the  
176 prevalence of persisting symptoms up to 110 days after COVID-19 of various severities, the  
177 five more common symptoms were fatigue (58%), headache (44%), attention disorder (27%),  
178 hair loss (25%) and dyspnea (24%), while agueusia, anosmia and memory loss were reported  
179 by 23%, 21% and 16% of the studies populations (24). Two studies evaluating hundreds of  
180 laboratory-confirmed COVID-19 outpatients have reported the prevalence of symptoms  
181 lasting more than 6 months after diagnosis: 33-39% participants with at least one symptom,  
182 14-55% with fatigue, 22% with dyspnea, and 14% with loss of sense of smell or taste (15,16).  
183 The differences between studies may be explained by various patients' selection criteria, data  
184 collection methods, and definitions of symptoms.

185 Strikingly, the proportion of COVID-positive patients with long-term symptoms was similar  
186 between the three surveyed periods. Our findings are supported by a few longitudinal studies,  
187 which analyzed the evolution of residual symptoms and showed a stable proportion after the  
188 acute phase and up to 7 months (7,25).

189 In our study 23% of COVID-positive required at least one additional medical visit for COVID-  
190 19-related symptoms, which is close to the proportion of 36% found in another study (16).  
191 These data show the burden on ambulatory health-care facilities related to post-COVID-19  
192 syndrome. However, we did not find a statistical difference in the proportion of patients  
193 requiring an additional medical consultation between COVID-positive and COVID-negative,  
194 which might be due to a lack of statistical power.

195 Our results shed more light on the association between SARS-CoV-2 infection and long-term  
196 symptoms. While some symptoms were more frequent in PCR-confirmed COVID-19  
197 outpatients, the prevalence of others was not different to SARS-CoV-2 PCR negative patients.  
198 In particular, the prevalence of headache and sleep disorder, two predominant persisting  
199 symptoms in COVID-negative patients, was similar between COVID-negative and COVID-  
200 positive. Both symptoms may originate from mixed etiologies including psychosocial factors  
201 and/or non-specific post-infectious consequences. The COVID-19 pandemic has greatly  
202 impacted our psychosocial behaviors due to confinement, social distancing, mask wearing and  
203 changing work conditions. Some symptoms may be a consequence of these unprecedented  
204 changes (26). Furthermore, long-term sequelae after an acute respiratory infection may not  
205 be limited to coronaviruses, as shown with severe H7N9 infection leading to lung disability  
206 and psychological impairment at 2 years of follow-up (27).

207 Another study evaluating 6-month sequelae in outpatients with COVID-19 included a small  
208 control group of healthy volunteers and showed that 33% of COVID-positive outpatients and  
209 5% of volunteers presented symptoms (15). However, the limited sample size (21 healthy  
210 volunteers) and their normal health status prevents comparison with our results. Another  
211 report also showed that 26% of seropositive health care workers present long-term symptoms  
212 8 months after mild COVID, while only 9% of seronegative do (28). Inclusion of patients

213 irrespective of the presence of symptoms (no or mild prior symptoms) might explain the lower  
214 prevalence compared to our results.

215 Overweight/obesity was an independent predictor of the presence of any long-term  
216 symptom, fatigue and dyspnea. Overweight and obesity are increasingly associated with poor  
217 outcomes in COVID-19. In a systematic review and meta-analysis of 22 studies and in a large  
218 CDC analysis in the United States population, overweight and/or obesity in COVID-19 were  
219 associated with an increased risk of hospital admission, invasive ventilation, and death,  
220 especially among patients younger than 60 years-old (29,30). Another study reported an  
221 association between body mass index and persisting symptoms after more than 28 days (31).  
222 The mechanisms responsible for post-COVID-19 syndrome are not understood yet and may  
223 be multiple (32,33). Long-term symptoms may be due to higher initial organ damages related  
224 to dysregulated inflammatory response. This may be true in people with overweight and  
225 obesity (34–36), since the adipose tissue has a high expression of angiotensin-converting  
226 enzyme 2 receptors and secretes pro-inflammatory cytokines.

227 While previous studies showed that male gender is a risk factor for severe outcome in COVID-  
228 19 (37), we identified female gender as a predictor for post-COVID-19 syndrome and  
229 specifically for persisting fatigue and smell or taste disorder. Although not always consistent,  
230 some studies have described an association between female gender and long-COVID (31),  
231 persisting fatigue (12–14), post-exertional polypnea (13), decreased rates of recovery (16),  
232 and anxiety or depression (14,16). Gender differences in immunity, as illustrated by the higher  
233 representation of women in autoimmune diseases (38), may explain divergent findings with  
234 COVID-19.

235 Our study has some limitations. First, most surveyed symptoms are subjective and prone to  
236 observer bias. Symptoms may also come from an intercurrent condition at the time of COVID-

237 19 diagnosis and not always represent sequelae of SARS-CoV-2 infection. However, inclusion  
238 of a symptomatic control group supports the association between some symptoms and SARS-  
239 CoV-2 infection. Furthermore, this reflects the clinical reality that physicians face in a post-  
240 COVID consultation. Since the prevalence of most symptoms was lower than 10%, the absence  
241 of difference may be due to a lack of statistical power to detect an association with COVID-19.  
242 Our study suffers from a selection bias due to SARS-CoV-2 test criteria (health care workers or  
243 presence of a risk factor of adverse outcome) at the time of the study, which may prevent  
244 generalization of our findings to the broad population. In addition, we included a SARS-CoV-2  
245 PCR negative control group, who had a slightly different clinical presentation (only patients  
246 with acute respiratory symptoms) compared to COVID-positive (any symptom suggestive of  
247 COVID-19). Furthermore, we cannot formally exclude that some COVID-negative had an  
248 undiagnosed SARS-CoV-2 infection due to a false negative PCR result. However, we used a  
249 validated SARS-CoV-2 RT-PCR test on a nasopharyngeal swab performed by a dedicated  
250 trained medical team to minimize technical and sample collection bias (19,39).

251 In conclusion, our study shows that more than half of outpatients with mild-to-moderate  
252 COVID-19 report long-term symptoms 3 to 10 months after diagnosis and that 21% seek  
253 medical care for this reason. These data suggest that post-COVID syndrome places a significant  
254 burden on society and especially healthcare systems. There is an urgent need to inform  
255 physicians and political authorities about the natural long-term course of COVID-19 in order  
256 to plan an appropriate and dedicated management of those with disabling persisting  
257 symptoms.

## **DECLARATIONS**

### **Acknowledgements**

We thank all the patients who accepted to participate and make this study possible.

We thank all healthcare workers of the triage center and of the emergency department of the University Hospital of Lausanne, who supported the study and managed COVID-19 suspected patients. We thank Nadia Cattaneo and Martin Delaloye who participated to patients' follow-up. We thank Tanguy Espejo and Luca Bosso who included patients in the COVID-negative group.

BG: study design, data interpretation and critical review of the manuscript.

OH, YMC, AG, PNC, BG: data interpretation and critical review of the manuscript.

EK: data analysis, interpretation, and critical review of the manuscript.

TB, SS: patients' inclusion, and critical review of the manuscript.

OO: microbiological data interpretation and critical review of the manuscript

MPO had full access to all the data in the study and takes responsibility for the integrity of the data and the accuracy of the data analysis.

### **Funding**

This work was supported by an academic award of the Leenaards Foundation (to NBB), the Infectious Disease Service and the emergency department of Lausanne University Hospital. The funding bodies had no role in the design of the study and collection, analysis, and interpretation of data and in writing the manuscript

**TABLES**

**Table 1: Characteristics of patients according to SARS-CoV-2 RT-PCR result (COVID-negative and COVID-positive).**

Characteristics	COVID-negative (N=89)	COVID-positive (N=418)	<i>P</i> value
<i>Demographics</i>			
Age in years	36 (29-47)	41 (31-54)	0.020
Female gender	57 (64%)	261 (62%)	0.776
Active smoking	27 (30%)	46 (11%)	<0.001
Health care worker	73 (82%)	281 (67%)	0.006
BMI (kg/m <sup>2</sup> )	24 (22-27)	24 (22-28)	0.412
<i>Comorbidities</i>			
Any comorbidity	32 (36%)	130 (31%)	0.372
Arterial Hypertension	8 (9.0%)	65 (16%)	0.109
Diabetes Mellitus	1 (1.1%)	22 (5.3%)	0.098
Cardiovascular Disease	5 (5.6%)	10 (2.4%)	0.157
Asthma	16 (18%)	43 (10%)	0.040
Malignancy (hematological/solid organ)	0 (0.0%)	15 (3.6%)	0.085
Chronic inflammatory disease	1 (1.1%)	13 (3.1%)	0.482
Overweight <sup>a</sup> or obesity	36 (40%)	189 (45%)	0.411
Obesity	11 (12%)	72 (17%)	0.260
Other comorbidities <sup>b</sup>	4 (4.5%)	12 (2.9%)	0.500
<i>Symptoms at initial consultation</i>			
Days from symptoms onset	2.0 (2.0-4.0)	3.0 (2.0-7.0)	0.088
Fever	52 (58%)	172 (41%)	0.003
Sore throat	35 (39%)	79 (19%)	<0.001
Rhinorrhoea	43 (48%)	205 (49%)	0.901
Smell or taste disorder	9 (10%)	73 (17%)	0.087
Cough	68 (76%)	305 (73%)	0.504
Dyspnea	49 (55%)	67 (16%)	<0.001
Myalgia/arthralgia	53 (60%)	249 (60%)	0.997
Diarrhea	19 (21%)	60 (14%)	0.099
<i>Signs at initial consultation</i>			
Temperature (°C)	36.9 (36.6-37.3)	37.2 (36.7-37.9)	<0.001
Heart rate (beats/min)	90 (78-98)	86 (75-98)	0.168
Respiratory rate (breath/min)	18 (16-20)	17 (15-20)	0.419
SpO <sub>2</sub> on ambient air (%)	97 (97-98)	97 (96-98)	0.405
<i>Microbiological information</i>			
SARS-CoV-2 cycle threshold value	-	22 (18-27)	-
<i>Outcome</i>			
Consultation for persisting symptoms	13 (15%)	87 (21%)	0.182

Data are number (%) of patients or median (interquartile range).

<sup>a</sup>“Any comorbidity” does not included overweight; <sup>b</sup>Other comorbidities: 7 Neurological Disease, 5 Chronic Kidney Disease, 4 Chronic Obstructive Pulmonary Disease, 4 Cirrhosis.

## Post-COVID-19 syndrome in outpatients: a cohort study

## Tables

*Missing data:* 1 BMI, 98 days from symptoms onset, 39 temperature, 84 heart rate, 310 respiratory rate, 41 SpO2 on ambient air, 7 SARS-CoV-2 cycle threshold value.

Two-sided chi-squared or Fisher tests were performed when comparing proportions, and Mann–Whitney U tests were performed for continuous variables.

BMI: body mass index; SpO2: oxygen saturation; SARS-CoV-2: severe acute respiratory syndrome coronavirus 2; RT-PCR: real time reverse transcriptase polymerase chain reaction.

**Table 2. Association between long-term symptoms (any and individualized symptoms) assessed at the time of phone survey and COVID positive status.**

Long-term symptoms	COVID-negative	COVID-positive	Bivariate analysis *		Multivariable analysis * °	
	(n=89)	(n=418)	OR (95% CI)	P value	aOR (95% CI)	P value
Any symptoms	33 (37%)	223 (53%)	1.94 (1.21-3.11)	0.006	2.04 (1.14-3.67)	0.017
Fatigue	15 (17%)	132 (32%)	2.28 (1.26-4.12)	0.006	2.14 (1.04-4.41)	0.039
Muscle weakness	2 (2.2%)	8 (1.9%)	0.85 (0.18-4.07)	0.837	0.65 (0.08-5.21)	0.688
Dyspnea	7 (7.9%)	66 (16%)	2.20 (0.97-4.96)	0.059	2.81 (1.10-7.16)	0.030
Dyspnea NYHA $\geq$ 2	4 (4.5%)	30 (7.2%)	1.64 (0.56-4.79)	0.363	1.11 (0.29-4.32)	0.881
Cough	3 (3.4%)	25 (6.0%)	1.82 (0.54-6.2)	0.334	1.16 (0.24-5.56)	0.849
Thoracic pain	4 (4.5%)	21 (5.0%)	1.12 (0.38-3.36)	0.834	1.11 (0.27-4.54)	0.886

Cardiovascular Disease	5 (2.6%)	5 (2.2%)	0.87 (0.25-3.06)	0.830	1.05 (0.27 to 4.09)	0.948
Chronic inflammatory Disease	5 (2.6%)	8 (3.6%)	1.41 (0.45-4.40)	0.549	1.18 (0.35 to 3.94)	0.790
<i>Timing of phone survey</i>						
>3 to 5 months	87 (45%)	103 (46%)	1.07 (0.72-1.57)	0.747	1.06 (0.65 to 1.73)	0.808
>5 to 7 months	47 (24%)	55 (25%)	1.03 (0.66-1.61)	0.894	1.05 (0.61 to 1.80)	0.856
>7 to 10 months	61 (31%)	65 (29%)	0.90 (0.59-1.37)	0.635	1.00 (reference)	

Data are number (%) of patients or median (interquartile range). \*symptoms associated with the presence of any long-term symptom. ° analysis adjusted for age, sex, smoking, overweight/obesity, diabetes, asthma, hypertension, cancer, cardiovascular disease, chronic inflammatory disease, period of the phone survey.

Missing data: 1 BMI

Odds ratio for age indicates the risk of the presence of any symptom per 5-year age increase.

OR: odds ratio; aOR: adjusted odds ratio; CI: confidence interval.

## FIGURE LEGENDS

### Figure 1: Study flow-chart

### Figure 2: Proportions of patients with long-term symptoms at the time of the phone survey.

**A)** Comparison between COVID-positive (positive SARS-CoV-2 RT-PCR) and COVID-negative (negative SARS-CoV-2 RT-PCR); **B)** Comparison between COVID-positive surveyed during three different period: Period 1: >3 to 5 months after SARS-CoV-2 diagnosis; Period 2: >5 to 7 months after SARS-CoV-2 diagnosis; Period 3: >7 to 10 months after SARS-CoV-2 diagnosis. Data are shown as proportions (%) with 95% confidence intervals.

### Figure 3: Factors associated with the presence of selected long-term symptoms (fatigue, smell or taste disorder, dyspnea and memory impairment) during the phone survey in COVID-positive patients.

Selected symptoms are those associated with COVID status.

Multivariable analysis adjusted for age, sex, smoking, overweight/obesity, diabetes, asthma, hypertension, cancer, cardiovascular disease, chronic inflammatory disease, period of the phone survey. Adjusted odds ratio for age indicates the risk of fatigue, smell/taste disorder, dyspnea or memory impairment per 5-year age increase.

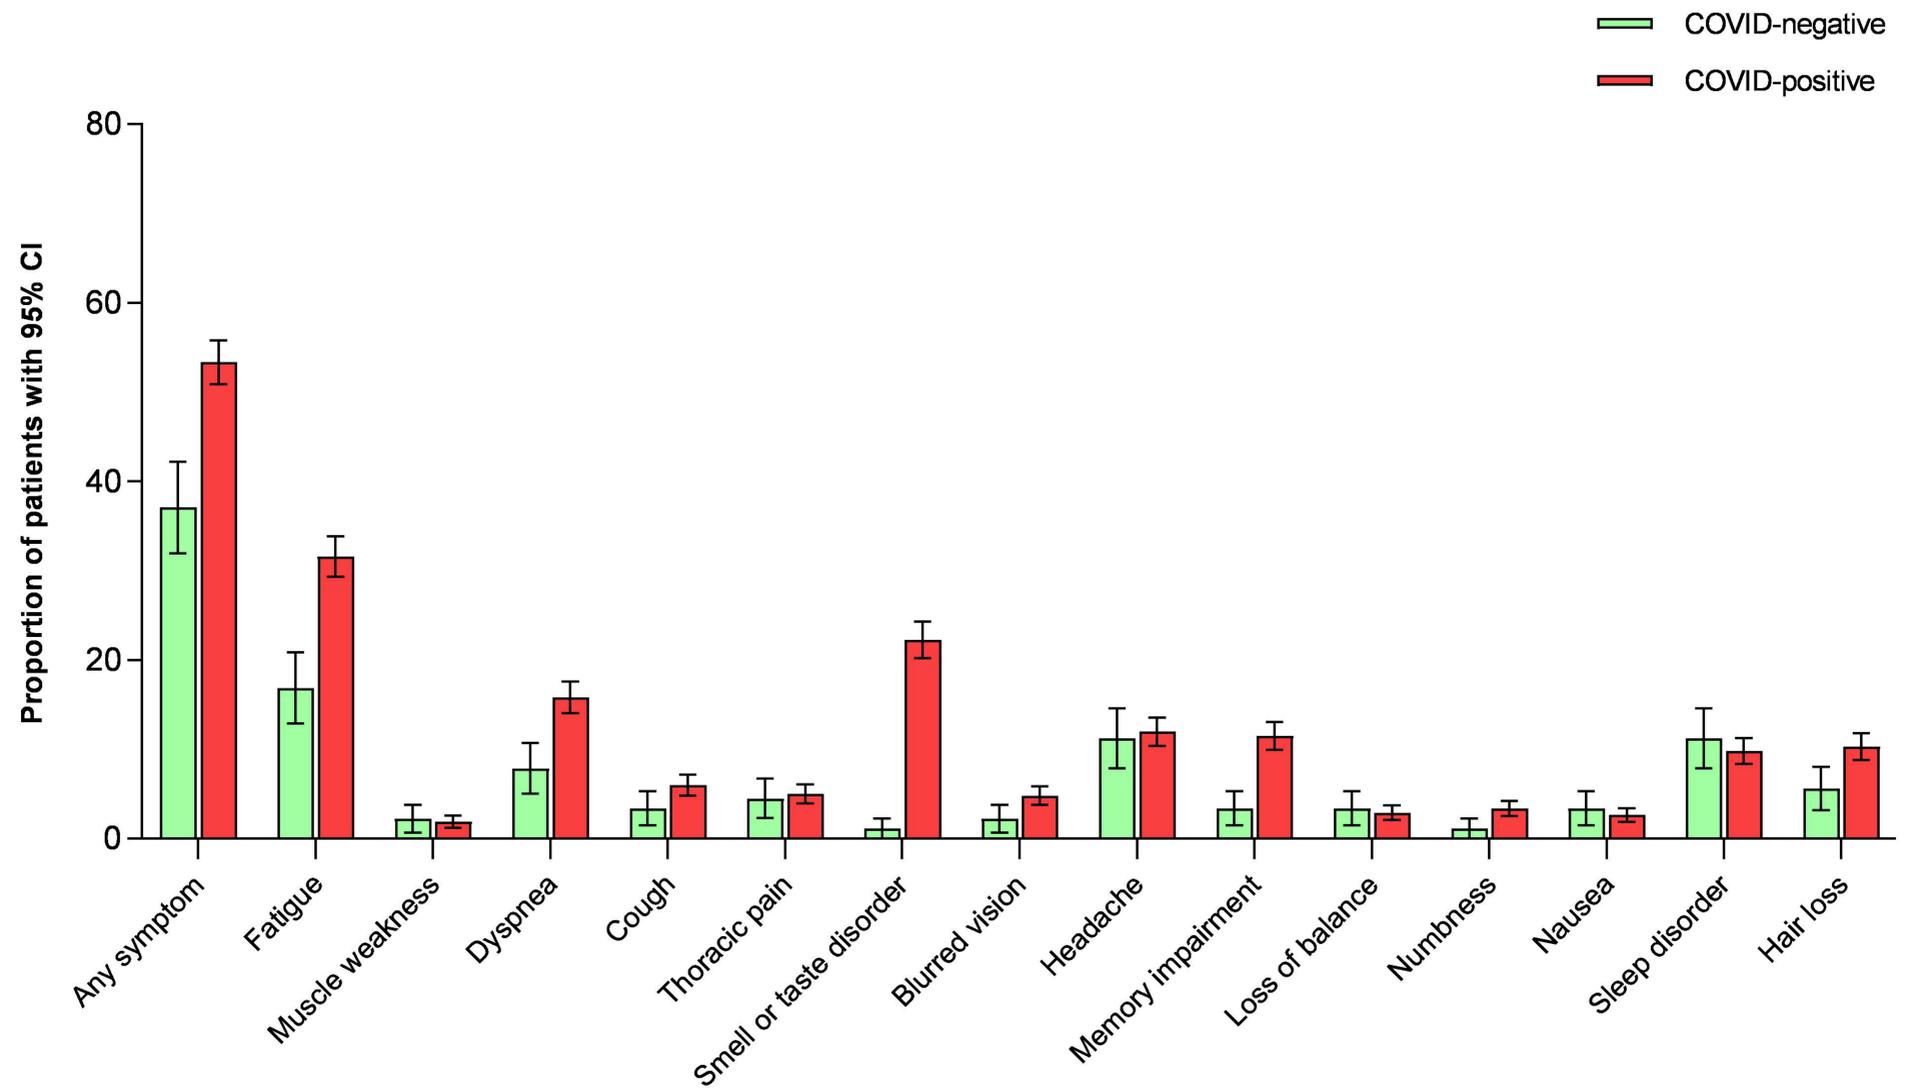

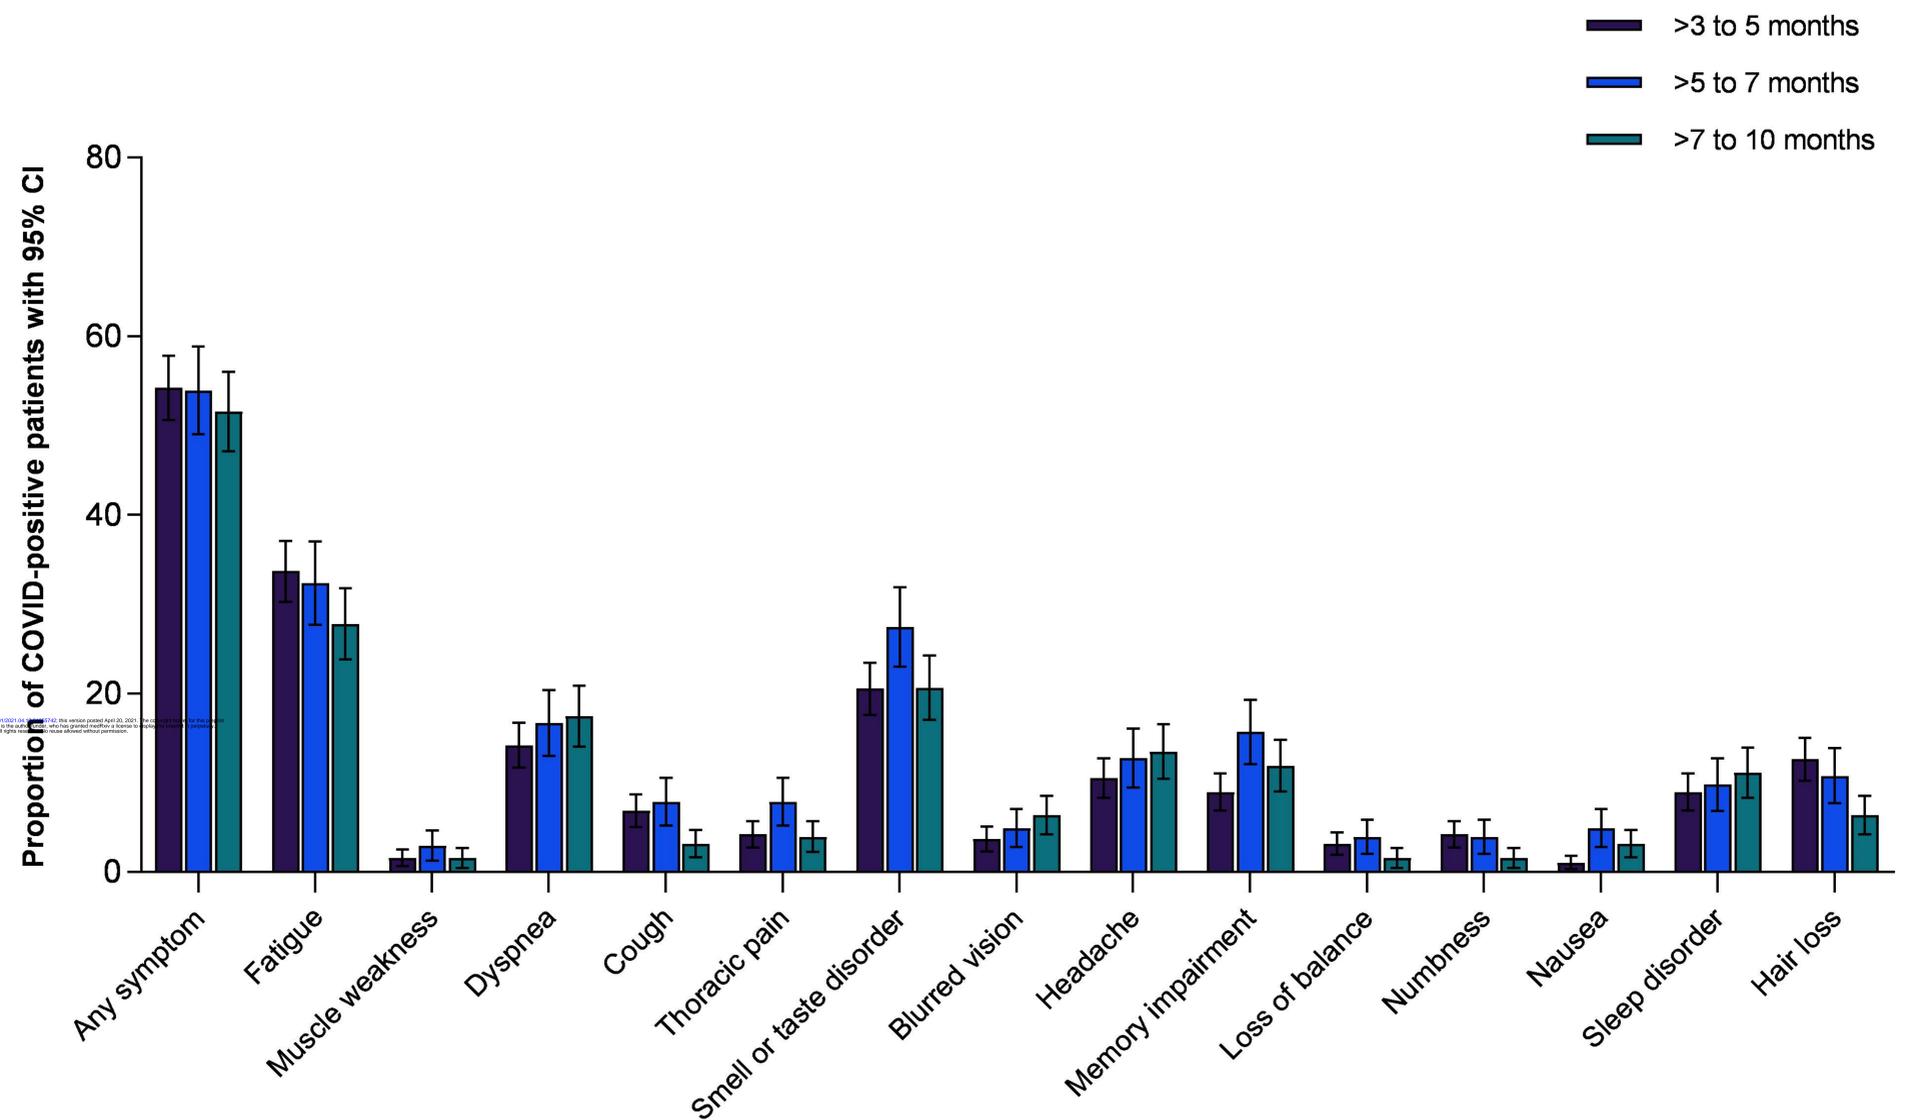

aOR: adjusted odds ratio; CI: confidence interval.

\* $p < 0.05$

956 patients with a positive RT-PCR SARS-CoV-2 result screened for inclusion

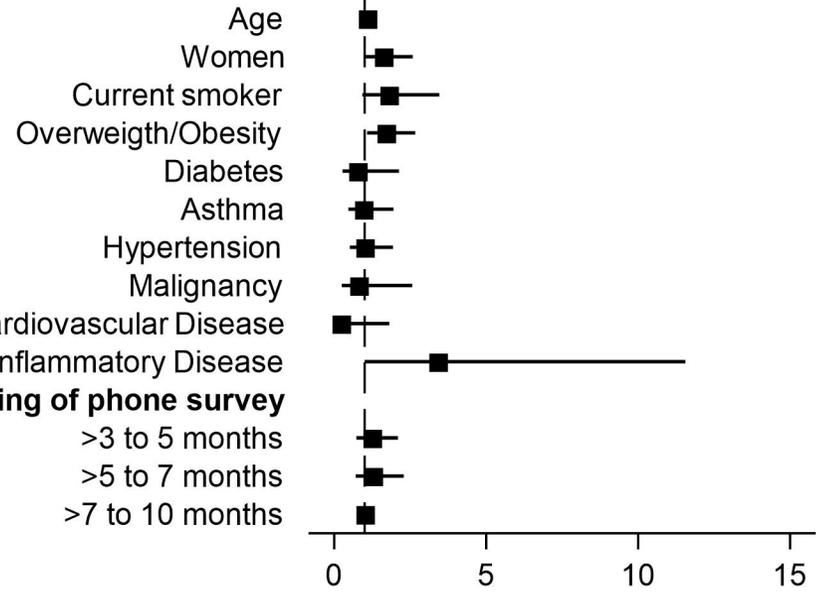

- 538 had at least one exclusion criteria:
- 198 were hospitalized within 30 days of their first visit
  - 174 were unreachable
  - 99 were included in another study
  - 39 declined to participate
  - 10 did not speak investigators' languages
  - 8 had an incomplete CRF
  - 4 died before the call
  - 3 were beyond study period limits
  - 2 were unable to consent
  - 1 had no documented health assessment at the date of test

418 COVID-positive included in the analysis
