ABSTRACT

Background: To inform vaccine prioritization guidance in Canada, we reviewed evidence on the magnitude of association between risk factors and severe outcomes of COVID-19.

Methods: We updated our existing review by searching online databases and websites for cohort studies providing multivariate adjusted associations. One author screened studies and extracted data. Two authors estimated the magnitude of association between exposures and outcomes as little-to-no (odds, risk, or hazard ratio <2.0, or >0.50 for reduction), large (2.0-3.9, or 0.50-0.26 for reduction), or very large (≥ 4.0 , or ≤ 0.25 for reduction), and rated the evidence certainty using GRADE.

Results: Of 11,734 unique records we included 135 reports. There is probably (moderate certainty) at least a large increase in mortality from COVID-19 among people aged 60-69 vs. <60 years (11 studies, n=517,217), with ≥ 2 vs. no comorbidities (4 studies, n=189,608), and for people with (vs. without): Down syndrome (1 study, n>8 million), type 1 and 2 diabetes (1 study, n>8 million), end-stage kidney disease (1 study, n>8 million), epilepsy (1 study, n>8 million), motor neuron disease, multiple sclerosis, myasthenia gravis, or Huntington's disease (as a grouping; 1 study, n>8 million). The magnitude of association with mortality is probably very large for Down syndrome and may (low certainty) be very large for age 60-69 years, and diabetes. There is probably little-to-no increase in severe outcomes with several cardiovascular and respiratory conditions, and for adult males vs. females.

Interpretation: Future research should focus on risk factors where evidence is limited in quantity (i.e., no or few small studies) or quality. This may include social factors, some rare conditions, the pediatric population, combinations of comorbidities that increase risk, and long-term outcomes.

Systematic review registration: PROSPERO #CRD42021230185.

INTRODUCTION

The novel coronavirus disease 2019 (COVID-19) became a worldwide public health concern in early 2020 [1]. About 20% of affected people will experience severe disease (e.g., requiring hospitalization), and some may have long-lasting medical complications [2]. In late 2020, Health Canada approved two vaccines for the prevention of COVID-19 (Pfizer-BioNTech COVID-19 Vaccine and Moderna COVID-19 Vaccine); this has been followed by the approval of others and continued review of emerging vaccine candidates [3]. As anticipated, vaccine distribution has been constrained by logistical challenges and limited supply [4-6], necessitating prioritization of populations for vaccination [5, 6].

The National Advisory Committee on Immunization (NACI) developed preliminary vaccine prioritization guidance in late 2020 “*for the efficient, effective and equitable allocation of safe, efficacious severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) vaccines in the context of staggered arrival of vaccines*” [5, 6]. In addition to reviewing evidence on the burden of illness and vaccine characteristics, NACI used its Ethics, Equity, Feasibility and Acceptability (EEFA) framework [7] and evidence-informed Equity Matrix [8] to achieve the goal of their prioritization guidance. The Equity Matrix considers biological and social risk factors (termed P²ROGRESS And Other Factors, informed by the PROGRESS-Plus model [9]) that may result in inequitable health outcomes across a population. The findings of a rapid review of risk factors for severe outcomes of COVID-19 conducted by our research group [10] helped populate the Equity Matrix, and informed NACI’s guidance. This initial review found increasing age (>60 years and particularly >70 years) to be among the strongest risk factors for severe outcomes of COVID-19 [10]. Since this time, numerous relevant primary studies have been published. To inform subsequent [11, 12] and future guidance statements, we performed an updated rapid review to determine the magnitude of association between P²ROGRESS And Other Factors and severe outcomes of COVID-19.

METHODS

Review Approach

Detailed methods are in our pre-defined protocol (PROSPERO #CRD42021230185), and described briefly herein. We followed traditional systematic review methods [13] with modifications to accommodate the expedited timeline needed to inform NACI’s guidance. Single experienced reviewers selected studies and extracted data, with piloting to maintain rigour. We restricted the scope to large, good quality studies with high relevance to Canada.

The eligibility criteria were informed by stakeholders at NACI and the Public Health Agency of Canada; these individuals were not involved in review conduct. This review is reported according to the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) statement [14].

Eligibility criteria

Table 1 details our eligibility criteria. We included published (or accepted for publication) cohort studies reporting multivariate adjusted associations between P²ROGRESS And Other Factors and severe outcomes of COVID-19 among: the general population; people with COVID-19; people hospitalized with COVID-19; people with severe COVID-19 (as defined by study authors); children in any of the aforementioned populations. Canadian reports of any design with any analysis type were eligible. For social risk factors, we included only Canadian reports because these were considered as most relevant by NACI.

We applied criteria at the selection stage to include only the most informative, good quality studies. Studies needed to take place in Organization for Economic Cooperation and Development (OECD) countries and include ≥1,000 participants (i.e., sufficiently powered for multivariate adjustment). Adjustment by age and sex was required in all studies, except Canadian reports. Findings for age and/or sex required adjustment for at least one pre-existing condition, and findings for most pre-existing conditions required adjustment for body mass index (BMI). After screening, we loosened our selection criteria for studies among children, requiring a sample size of ≥300 participants and adjustment by age and sex (but not BMI), as limited evidence was available for this population.

When no primary studies were located on a risk factor of high relevance to NACI, we included systematic reviews with broader selection criteria.

Literature search and study selection

Full details of the literature search are in Appendix 1. A research librarian searched online databases (Ovid Medline® ALL 1946-, Epistemonikos COVID-19 in L-OVE Platform for individual predictors of outcomes; 2-3 December 2020) and websites suggested by NACI (6 January - 3 February, 2021). We updated the Medline and website searches in April 2021 for the pediatric population, immune compromise, and autoimmune conditions, to further inform NACI's guidance for risk factors. We exported records to Endnote X9 (Clarivate Analytics, Philadelphia, PA), removed duplicates and pre-

prints, then uploaded the records to Covidence systematic review platform (<https://www.covidence.org/>). After piloting, a single experienced reviewer screened each record by title and abstract, then by full text. A second reviewer was consulted as needed.

Following screening, gaps in evidence (i.e., no study meeting our criteria) were apparent for asplenia/splenic dysfunction, cystic fibrosis, sickle cell disease, β-thalassemia, and learning disability (potentially important based on inclusion in priority lists from other jurisdictions [15-18]). To locate evidence for these, we scanned all studies excluded based on sample size (<1,000 participants), preprints, and systematic reviews that we had located during our scoping exercises (September, 2020) using Smart Searches in Endnote. On 18 February 2021, we conducted targeted searches in Ovid Medline® ALL 1946- for studies and reviews on these risk factors.

Data extraction

After piloting, a single reviewer extracted data from each study into Excel (v. 2016; Microsoft Corporation, Redmond, WA): study and population characteristics, exposures, covariates, outcomes and their definitions, findings for multivariate associations. We held regular team meetings to troubleshoot and ensure consistency. Because we attempted to include only good quality studies, we did not formally assess their quality, but recorded potential risk of bias concerns (Appendix 2) for consideration during assessment of the certainty of evidence.

Synthesis and drawing conclusions

Appendix 2 details our approach to synthesis and drawing conclusions. Results from the Canadian studies, none of which met the criteria of having sufficiently adjusted analysis, were not included in the main synthesis and are reported separately. We did not pool findings statistically for any outcome, due to large heterogeneity in comparisons and measures of association, and at least some overlap in populations across studies. Instead, two reviewers reached consensus on a best estimate of the magnitude of association for each outcome (based on adjusted odds [aOR], risk, or hazard ratios): little-to-no (<2.0, or >0.5 for reduction), large (2.0-3.9, or 0.5-0.26 for reduction), or very large (≥ 4.0 , or ≤ 0.25 for reduction). Two reviewers assessed the certainty of evidence for each exposure-outcome association, informed by elements of the Grading of Recommendations, Assessment, Development and Evaluations approach [19].

Ethics approval

Ethics approval was not required.

RESULTS

Included studies

Of 11,734 unique records identified, we included 135 reports (Figure 1) [20-154]. Full text exclusions are listed at [<https://doi.org/10.7939/DVN/VDELOG>]. We included one systematic review of case series for β-thalassemia [119]. No studies or reviews were located with relevant findings for asplenia/splenic dysfunction, cystic fibrosis, sickle cell disease, or learning disability. No study reported on long-term outcomes. Table 2 shows a summary of the characteristics of the studies presenting multivariate adjusted findings that were included in the main synthesis (n=124) [20-121, 131-152]; full details by study, including 11 Canadian reports [122-130, 153, 154], are in Appendix 3. The studies contributing multivariate associations originated primarily from the United States (n=55), the United Kingdom (n=15), and Mexico (n=13), and included more than 76 million participants (median 5,327; range 34 to 61,414,470).

Associations between risk factors and outcomes

Based on stakeholder input, we considered people with confirmed COVID-19 to be the population of highest relevance, thus have focused on these in our presentation of findings. When no data were available from the COVID-19 population for a risk factor-outcome comparison, we relied on findings from the general population. Table 3 summarizes the risk factors showing large or very large multivariate-adjusted associations with severe outcomes. Appendix 2 includes findings for all risk factors and populations investigated in the review. Data supporting the conclusions are available at [<https://doi.org/10.7939/DVN/VDELOG>].

The certainty of evidence was moderate for at least a large increase in mortality from COVID-19 for people aged 60-69 years versus <60 years (11 studies, n=517,217) [24, 48, 63, 68, 71, 84, 92, 93, 98, 101, 106, 113], people with two or more versus no comorbidities (4 studies, n=189,608) [48, 59, 101, 105], and for people with (versus without): Down syndrome (1 study, n>8 million) [35], type 1 and 2 diabetes (1 study, n>8 million) [35], end-stage kidney disease (1 study, n>8 million) [35]; epilepsy (1 study, n>8 million) [35]; motor neuron disease, multiple sclerosis, myasthenia gravis, or Huntington's disease (as a

grouping; 1 study, n>8 million) [35]. The magnitude of association with mortality is probably (moderate certainty) very large for Down syndrome, and may (low certainty) be very large for age 60-69 years, and diabetes. We located no evidence on the combination of conditions that would place people with two or more comorbidities at increased risk.

The certainty of evidence was low for a large increase in mortality or hospitalization among: people with cerebral palsy (1 study, n>8 million); major psychiatric disorder (schizophrenia, schizoaffective disorder, or bipolar disorder, with drug use for the condition in the past 6 months; 1 study, n=11,122) [105]; obesity class III ($BMI \geq 40 \text{ kg/m}^2$) versus normal weight (1 study, n=1,612) [113]; Parkinson's disease (1 study, n>8 million) [35]; sickle cell disease or severe immunodeficiency (1 study, n>8 million) [35]; solid organ transplant (2 studies, n=18,038 for mortality [105, 113]); transplant of any type (3 studies, n=24,227 for hospitalization [49, 64, 105]); kidney transplant (1 study, n>8 million) [35]; recent bone marrow or stem cell transplant (1 study, n>8 million) [35]; metastatic cancer among those <70 years (2 studies, n=38,377) [58, 113]; current or recent (past year) chemotherapy or radiotherapy (past 6 months; 1 study, n>8 million); vasculitis (1 study, n=4,543,249) [135]; pregnancy (any stage; 1 study, n=409,462) [34]; frailty (2 studies, n=404,079) [77, 95]. The magnitude of association with mortality may (low certainty) be very large for recent chemotherapy. There was moderate certainty for a large increase in hospitalization with previous cerebrovascular accident (2 studies, n=12,376) [49, 115].

Among children, there was evidence of moderate certainty for a large increase in hospitalization among those having two or more versus no chronic conditions (1 study, n=804) [137], and evidence of low certainty for a large increase in mortality and hospitalization for children of Black versus White non-Hispanic race/ethnicity (1 study, n=12,198) [146]. There was low certainty for a large reduction in hospitalization for children 0-19 years versus adults aged 50-59 years (1 study, n=2,199) [105], and a large increase in hospitalization for children with one versus no chronic conditions (1 study, n=790) [137], and specifically for children with versus without immunodeficiency or immunosuppression (2 studies, n=21,875) [82, 138], and hypertension (1 study, n=21,116) [82]. Additionally, there was evidence of low certainty for a large increase in severe outcomes (ICU admission, mechanical ventilation, or 'severe disease') among children with versus without: one or more chronic conditions (1 study, n=759 for mechanical ventilation and severe disease [138]; 2 studies, n=1,341 for ICU admission), asthma (1 study, n=21,116) [82], endocrine conditions (1 study, n=5,374) [133], metabolic conditions (1 study, n=5,374) [133], and malignancy (1 study, n=5,374) [133].

There were several risk factors with moderate certainty evidence for little-to-no association with increased severity of COVID-19, for example many pre-existing conditions (notably several cardiovascular and respiratory conditions), and for adult males versus females (Appendix 2).

Table 4 shows the risk factors identified in Canadian reports and potential associations with severe outcomes of COVID-19. All data collected from these studies are in Appendix 2. This evidence was used primarily to draw conclusions about social factors, and was often descriptive and lacking adjustment for important covariates. These studies showed the potential for a large increase in mortality among people living in long-term care (6 reports, n≈2 million) [122, 123, 125, 127, 128], visible minority groups (mainly South Asian, Chinese, Black, Filipino, Latin American, Arab, Southeast Asian, West Asian, Korean, Japanese; 1 report, n=8,796) [129], and people living in the general population (off-reserve) versus First Nations people living on-reserve (1 report, n=9,715) [124].

INTERPRETATION

This review provides a methodologically rigorous synthesis of a large volume of emerging evidence on factors associated with severe outcomes of COVID-19. There is now strong (moderate certainty) evidence of at least a large increase in mortality from COVID-19 among people aged 60 to 69 versus <60 years (and over 70 years from our previous review [117]), people having two or more versus no comorbidities, and for people affected by (versus unaffected): Down syndrome; type 1 and type 2 diabetes; end-stage kidney disease; epilepsy; motor neuron disease, multiple sclerosis, myasthenia gravis, or Huntington's disease.

Our earlier review suggested a potentially large increase in severe outcomes among males versus females, and for people with some pre-existing conditions (heart failure, dementia, liver disease) [10]. The current evidence no longer supports this increased risk, underscoring the importance of interpreting low certainty evidence cautiously, and of continually reviewing emerging data to support vaccine prioritization guidance. There is now relatively strong evidence for little-to-no increase in severe outcomes for several pre-existing diseases, notably many cardiovascular and respiratory conditions. In contrast, many jurisdictions have identified people with these conditions as priorities for vaccination [15-18]. The reason for this is not fully clear, because the evidence on which prioritization decisions are made is often not publically available, and such decisions are informed by multiple considerations (e.g.,

local epidemiology, ethics, risk-benefit analyses, vaccine characteristics and availability [5, 6, 155]) and varying levels of evidence.

A large reliance on unadjusted data may provide some explanation [156]. The data synthesized within this review have the advantage of accounting for the impact of multiple co-existing conditions, social and demographic factors. For example, in a large study ($n=418,794$) of the general population in the United Kingdom [94], a large increase in hospitalization among people with heart failure (OR 2.24) and chronic obstructive pulmonary disease (OR 2.67) was observed. Following adjustment for age, sex, social factors, BMI, and other chronic conditions, these associations were substantially attenuated to the range of little-to-no association (aOR 1.09 and 1.51, respectively) [94]. We observed similar relationships in other studies. The thresholds of magnitude used to define ‘large’ and ‘very large’ increases in severe outcomes may also impact the conditions prioritized. Finally, there are some rare conditions (e.g., thalassemia, splenic dysfunction) for which to our knowledge, no large and well-adjusted studies have been published. In these cases, governing bodies may need to rely on evidence available for other infectious diseases, or from smaller cohorts suggesting the potential for increased risk [18, 157-160].

The findings of this review, among other considerations, have informed NACI’s vaccine prioritization guidance. Emerging data should continue to be synthesized to improve on the certainty of evidence for some populations and outcomes. Though children seem to be at reduced risk of severe outcomes of COVID-19 compared to adults [161], there are few large, well-adjusted analyses available for children. Therefore, the current evidence about risk factors within this population is of low certainty. However, data is beginning to accumulate; we located six new eligible studies in our April 2021 update search to help inform NACI’s guidance [133, 137, 138, 146, 150, 154]. As we did not locate data to inform the combination of comorbidities that may place a person at increased risk of severe outcomes, a focus on this in future research would be valuable. Information from the development of risk prediction models may also provide insight [162]. Finally, while we looked for studies examining a range of factors based on the “P²ROGRESS And Other Factors” framework, the majority of studies focused on medical comorbidities. High quality research on P²ROGRESS And Other Factors would allow for a more nuanced approach to optimize vaccine rollout [155].

Limitations

Because we used a rapid approach, there is a small possibility of undetected errors in study selection or data extraction. We mitigated this through piloting and engaging experienced reviewers. Though the findings are most applicable to OECD countries, we often relied on data largely from the United States and other countries without universal healthcare systems. We located no evidence relevant to long-term outcomes.

Conclusion

There is strong evidence to support at least a large increase in mortality from COVID-19 among older adults aged 60 to 69 years versus <60 years; people having two or more versus no comorbidities; and for people affected by Down syndrome; type 1 and 2 diabetes; end-stage kidney disease; epilepsy; and motor neuron disease, multiple sclerosis, myasthenia gravis, or Huntington's disease (as a grouping). Future research should focus on risk factors where evidence remains limited (no studies) or of low quality, the pediatric population, combinations of comorbidities that may increase risk, and long-term outcomes.

ACKNOWLEDGMENTS

We thank Kelsey Young, Kelly Farrah, Shainoor Ismail, and Matthew Tunis from the NACI Secretariat for expert input into the review's scope and eligibility criteria, and for reviewing the initial draft of the manuscript; Sharon Bartholomew, Louise McRae, Anne-Marie Robert, Samina Aziz, Alain Demers, Catherine Pelletier, Cynthia Robitaille, Larry Shaver, Helene Gardiner, and Dianne Zakaria from the Public Health Agency of Canada for input into the necessary adjustment variables for analyses of chronic diseases; Elizabeth Dennett and Erica Wright for developing and running literature searches; Andrew Beck for assistance with screening; and Mackinna Hauff for article retrieval and document formatting.

CONTRIBUTOR'S STATEMENT

MG contributed to the conception and design of the work, selection of studies, data extraction, analysis and interpretation of data, and drafted the initial version of the manuscript. JP contributed to the conception and design of the work, analysis and interpretation of data, and revised versions of the manuscript. AW, SG, SR, BZ, and AG contributed to the selection of studies, data extraction, organizing data for analysis, and revised versions of the manuscript. LH contributed to the conception and design of the work, methodological oversight, interpretation of findings, and revised versions of the manuscript.

All authors approved of the final version of the manuscript submitted and agree to be accountable for all aspects of the work.

ROLE OF FUNDERS

The funders had no role in the conduct of the study nor decision to submit for publication.

Table 1. Eligibility criteria for inclusion of studies in the review ^a

	Inclusion and exclusion criteria
Study design	<p>Include:</p> <ul style="list-style-type: none"> - Prospective and retrospective cohort studies, including registry-based studies (may be published as a letter); government reports; pre-prints that have been accepted for publication - Canadian reports of any design - Systematic reviews, only for risk factors of high relevance to NACI where no primary studies are found <p>Exclude: Pre-prints that have not been accepted by a peer-reviewed journal, commentaries, editorials</p>
Sample size	Primary studies were required to include at least 1,000 participants (≥ 300 for studies of children). There was no sample size requirement for systematic reviews.
Population	<p>Include: People of any age in the general population; with COVID-19 infection (laboratory-confirmed or epidemiologically linked); hospitalized with COVID-19; with severe COVID-19 (as defined by study authors); children in any of the aforementioned populations.</p> <p>Exclude: Populations with other pandemic-related infections, if data for COVID-19 cannot be isolated. People with COVID-19 that is not laboratory-confirmed or epidemiologically linked. When unclear, we included studies if it appeared that the large majority (i.e., $\geq 90\%$) would be confirmed cases.</p>
Exposure	<p>Include: Any P²ROGRESS And Other Factors including but not limited to age; gender identity or sex; disease/condition or disability; number of comorbidities; social factors (place/state of residence; race, ethnicity, immigrant/refugee status, Indigenous identity, culture, language; occupation; religion, belief system; education, literacy; socioeconomic status; social capital); other (e.g., health behaviours).</p> <p>Exclude: Exposures that constitute laboratory findings, vital signs, or symptoms occurring after COVID-19 infection; any other exposures not of interest to NACI.</p>
Comparator	<p>Include: (a) no exposure to the P²ROGRESS And Other Factors; (b) the same P²ROGRESS And Other Factors experienced differently or to a different extent (e.g., different age group). When included, systematic reviews did not require a comparator.</p> <p>Exclude: Variations in disease severity within the pre-existing disease/condition or disability category (i.e., only interested in presence/absence of this risk factor); studies without a comparator.</p>
Outcome	<p>Include: Epidemiologic or analytic data from Canadian reports; from all other studies, magnitude of association (based on multivariate analysis adjusting for at minimum age and sex)[*] between the exposure and any of hospitalization; in-hospital length of stay; ICU admission; ICU length of stay; mechanical ventilation; mortality (all-cause or case fatality); severe disease (composite outcomes as defined by study authors); need for rehabilitation; stroke; kidney, liver, or cardiac injury; generic functionality and/or disability (composite scores of validated scales); generic quality of life (composite scores of validated scales).</p> <p>[*]Only age and sex adjustment required for studies of children. Age and sex needed to be adjusted for at least one pre-existing condition. Pre-existing conditions (except immunocompromised, autoimmune, neurologic, mental health, frailty) needed to be adjusted for body mass index.^b</p> <p>Exclude: All other outcomes; disease-specific functionality, disability, or quality of life; crude / unadjusted associations; studies where the focus is symptoms, biomarkers, clinical variables collected after disease onset.</p>
Timing	Any length of follow-up; at least 28 days for mortality
Setting	<ul style="list-style-type: none"> - For social risk factors among adults, only Canadian studies - For all other risk factors, Organization for Economic Cooperation and Development countries: https://www.oecd.org/about/document/list-oecd-member-countries.htm - Systematic reviews could include studies from any country
Language	English or French

^a The main scope differences versus the original review were: addition of a sample size requirement; inclusion of Canadian reports of any design; addition of children as an important population; inclusion of Canadian reports only for social factors; requirement of adjustment for more than age and sex for some risk factors; addition of organ injury and long-term outcomes of relevance to NACI.

^b Decisions for adjustment by body mass index were informed by the findings of our previous review and expert input from the Public Health Agency of Canada.

Table 2. Summary of study characteristics for the studies contributing to the main synthesis, n=124 ^a

Characteristics	Number of studies	Proportion of studies (%)
STUDIES		
Design		
Retrospective cohort	93	75.0
Prospective cohort	29	23.4
Nested case-control	1	0.8
Systematic review ^b	1	0.8
Setting		
United States	55	44.4
United Kingdom	15	12.1
Mexico	13	10.5
Italy	9	7.3
Korea	6	4.8
Spain	6	4.8
Denmark	4	3.2
France	3	2.4
Other ^c	16	12.9
Funding source		
Non-industry	59	47.5
Industry	3	2.4
No funding	28	22.6
Not reported	36	29.0
PARTICIPANTS ^d		
Number of participants, median (range)	5,327 (34 to 61,414,470)	
Mean or median age in years, median (range)	61.6 (5.0 to 78.6)	
Sex/gender, median % male (range)	49.9 (0 to 94.0)	
Population analyzed		
General population	10	8.1
People with COVID-19	60	48.4
Hospitalized with COVID-19	63	50.8
With severe disease (in ICU or mechanically ventilated)	9	7.3
COVID-19 ascertainment		
RT-PCR	95	76.6
Laboratory confirmed (unspecified test)	25	20.2
Antigen test	3	2.4
Nucleic acid test	2	1.6
Rapid antibody test	2	1.6
EXPOSURES		
Pre-existing conditions	96	77.4
Gender identity/sex	71	57.3
Age (60-69 versus <60 years)	42	33.9
Other (health behaviours)	27	21.8
Number of comorbidities	22	17.7
Children	11	8.9
Exposure - occupation	4	3.2
Pregnancy	4	3.2
OUTCOMES		
Hospitalization	37	29.8

Characteristics	Number of studies	Proportion of studies (%)
In-hospital length of stay	4	3.2
ICU admission	27	21.8
ICU length of stay	1	0.8
Mechanical ventilation	22	17.7
Acute kidney injury	8	6.5
Ischemic stroke	1	0.8
Severe disease	28	22.6
Mortality	89	71.8

COVID-19=novel coronavirus disease 2019; ICU=intensive care unit; RT-PCR=reverse transcription polymerase chain reaction

^a Categories do not all add to 100%, as it is possible for studies to report on more than one category (e.g., used more than one COVID-19 ascertainment method, analyzed more than one population).

^b Included for β-thalassemia as no primary studies meeting the selection criteria were located.

^c Includes Belgium (n=1), Germany (n=2), Ireland (n=1), multi-country (n=3), Netherlands (n=1), Sweden (n=2), Turkey (n=2), UK and Italy (n=1).

^d 24 studies did not report on patient mean or median age, one study in children did not report on patient sex/gender.

Table 3. Risk factors identified that have large or very large associations with severe outcomes of COVID-19 and the corresponding level of certainty in the association

Risk factor (among people with COVID-19 unless otherwise specified)	Outcome of interest	Magnitude of association ^a (certainty in association) ^b
Age		
60-69 vs. <60 years	Hospitalization	Large (moderate)
	Mechanical ventilation	Large (low)
	Severe disease	Large to very large (low)
	Mortality	Large/very large (moderate/low)
Pre-existing conditions		
2 or more vs. no comorbidities	Hospitalization	Large (moderate)
	ICU admission	Large (low)
	Mechanical ventilation	Large (low)
	Mortality	Large (moderate)
Down syndrome ^c	Hospitalization	Large/very large (moderate/low)
	Mortality	Very large (moderate)
Type 1 diabetes ^c	Mortality	Large/very large (moderate/low)
Type 2 diabetes ^c	Mortality	Large/very large (moderate/low)
End-stage kidney disease ^c	Mortality	Large (moderate)
Epilepsy ^c	Mortality	Large (moderate)
Motor neuron disease, multiple sclerosis, myasthenia gravis, or Huntington's disease ^{c, d}	Mortality	Large (moderate)
Chemotherapy in the past 12 months (Grade A-C) ^{c, e}	Mortality	Large/very large (low)
Radiotherapy in the past 6 months ^c	Mortality	Large (low)
Among people <70 years, metastatic cancer	Mortality	Large (low)
Parkinson's disease ^c	Mortality	Large (low)
Sickle cell disease or severe immunodeficiency ^c	Mortality	Large (low)
Solid organ transplant	Mortality	Large (low)
Transplant (any, including solid organ)	Hospitalization	Large (low)
Kidney transplant (due to stage 5 kidney disease) ^c	Mortality	Large (low)
Recent bone marrow or stem cell transplant ^c	Mortality	Large (low)
Vasculitis ^c	Hospitalization	Large (low)
Major psychiatric disorder (schizophrenia, schizoaffective disorder, or bipolar disorder) ^f	Mortality	Large (low)
	Hospitalization	Large (low)
Cerebral palsy ^c	Mortality	Large (low)
Diabetes (any type) in females	Mortality	Large (low)
Obesity class III vs. normal weight	Mortality	Large (low)
Previous cerebrovascular accident	Hospitalization	Large (moderate)
Obesity (all classes) vs. normal weight ^c	Hospitalization	Large (low)
Obesity class III vs. lower body mass index	Hospitalization	Large (low)
Obesity hypoventilation syndrome	Mechanical ventilation	Large (low)
Pregnancy (any stage)	Hospitalization	Large (low)
	ICU admission	Large (low)
	Severe disease (pneumonia)	Large (low)
Frailty ^{c, g}	Hospitalization	Large (low)
Chronic kidney disease	Hospitalization	Approaching large (low)
Diabetes (any)	Hospitalization	Approaching large (low)

Risk factor (among people with COVID-19 unless otherwise specified)	Outcome of interest	Magnitude of association ^a (certainty in association) ^b
Children (as defined by individual studies)		
Children (0-19 years) vs. adults (50-59 years)	Hospitalization	Large reduction (low)
Age <1 month vs. >1 month	ICU admission	Large (low)
Immunodeficiency or immunosuppression (unspecified reason)	Mortality	Large to very large (low)
	Hospitalization	Large (low)
Hypertension	Hospitalization	Large (low)
2 or more vs. no chronic conditions ^h	Hospitalization	Large (moderate)
1 vs. no chronic conditions ^h	Hospitalization	Large (low)
1 or more vs. no chronic conditions ⁱ	ICU admission	Large (low)
	Mechanical ventilation	Large (low)
	Severe disease	Large (low)
Asthma	ICU admission	Large (low)
Endocrine condition ^j	Severe disease	Large (low)
Metabolic condition ^j	Severe disease	Large (low)
Malignancy ^j	Severe disease	Large (low)
Black race/ethnicity vs. White non-Hispanic	Mortality	Large (low)
	Hospitalization	Large (low)
Risk of exposure - occupation		
Healthcare workers (vs. non-healthcare workers)	Hospitalization	Large reduction (low)
	ICU admission	Large reduction (low)

ICU=intensive care unit; vs.=versus

^a Magnitude of associations are shown as large (OR or RR ≥ 2.00 , or ≤ 0.5 for reduction) or very large (OR or RR ≥ 4.00).

^b Confidence in the magnitude of the associations was determined by considering primarily consistency in findings across studies, directness of the setting and risk factors (e.g., type of healthcare system, uncertainty about risk factor clearly matching review criteria), precision (e.g., confidence intervals indicating possibility of little to no association), and potential risk of bias. Low confidence indicates that there may be an association and moderate means that the evidence indicates that there probably is an association of the magnitude stated.

^c The denominator for these risk factors is the general population. These were included when findings for the risk factor-outcome comparison were not available from studies of populations with COVID-19.

^d These conditions were grouped within a single study; evidence for the individual conditions is either unavailable or of lower certainty.

^e There was evidence of a large to very large increase in mortality with grades B and C chemotherapy from one large study. However, the stages of chemotherapy were not defined, and could not be ascertained from the study's authors. In the absence of adequate information, we have grouped all stages of chemotherapy (A, B, and C) together for analysis.

^f Defined by hospital discharge diagnosis, in combination with drug use (filled a prescription) for the condition in the past 6 months.

^g General population sample that may include community and non-community dwelling people. Measured on scales that include items such as weight loss, exhaustion, physical activity, walking speed, grip strength, overall health, disability, presence of disease, dementia, falls, mental wellbeing.

^h Includes congenital malformations, asthma, epilepsy, complex genetic syndromes, endocrine disorders, cancers, hematologic diseases, rheumatic diseases, autoimmune disease, autism or neurologic development impairment, gastrointestinal diseases, liver disease, renal disease, genitourinary diseases, cystic fibrosis or other chronic lung diseases, metabolic disorders, hydrocephalus, severe obesity, hypertension, otolaryngolic diseases, pregnancy, and 'complex chronic conditions'.

ⁱ Includes congenital malformations, asthma, epilepsy, complex genetic syndromes, endocrine disorders, cancers, hematologic diseases, rheumatic diseases, autism or neurologic development impairment, gastrointestinal diseases, genitourinary diseases, renal disease, cystic fibrosis or other chronic lung diseases, metabolic disorders, hydrocephalus, severe obesity, otolaryngolic diseases.

^j Categorizations according to ICD-10-CM codes and the Pediatric Medical Complexity Algorithm.

Table 4. Risk factors identified in Canadian reports and potential associations with severe outcomes of COVID-19

Risk factor	Reports (participants)	Conclusion
Social factors		
Living in long-term care	6 (\approx 2 million)	Probably associated with a large increase in mortality; the association may be very large for those in their 60s and 70s.
Being part of a visible minority population ^a	1 (8,796)	May be associated with increased mortality; magnitude uncertain and findings rely on ecological data and did not account for important covariates.
Living on a First Nations reserve	1 (9,715)	Rates of hospitalization and mortality appear lower compared to living off-reserve. The evidence does not account for potentially important covariates such as age.
Being a healthcare worker	2 (23,101)	Among those aged 30-70 years, may be associated with a large reduction in hospitalization, ICU admission, and mortality. Among healthcare workers, males appear to have higher rates of hospitalization, ICU admission, and mortality than females. Analyses did not account for important covariates.
Homelessness	2 (18,224)	Very uncertain about associations with mortality.
Being a homeless shelter worker	1 (1,734)	Very uncertain about associations with mortality.
Age and gender identity/sex		
Age 60-69 vs. <60 years	5 (235,481)	May be associated with a large increase in hospitalization, ICU admission, and mortality. For mortality there may also be a large association when compared to 50-59 years. The magnitude of association appears to account for pre-existing medical conditions and seems similar between sexes, though absolute rates are high among men in all age groups, particularly among those not residing in long-term care or delivering healthcare. Findings for hospitalization and ICU admission may be most applicable to those living outside of long-term care as there has been limited transfer to hospital and ICU from this setting.
Male vs. female	2 (11,259)	Rates of hospitalization and ICU admission appear to be lower among females >30 years; after excluding health care workers, long-term care residents, and school/daycare workers and attendees, the reduction in hospitalization and ICU admission was only observed in those >50 years. Case fatality appears to be lower among females than males in the same age group.
Pre-existing conditions		
One vs. no comorbidities	2 (15,875)	In all age groups, may have little-to-no association with mortality.
Two or more vs. <2 comorbidities	1 (6,350)	Among people aged 60-79 years, may be associated with a large increase in mortality. Study data were not adjusted for important covariates like residing in long-term care. Findings for people <60 years were limited by small sample size.
Compromised immunity	1 (1,734)	May be associated to some extent with an increase in mortality; the magnitude of association is uncertain due to a wide confidence interval. This association was adjusted for age, long-term care residency, smoking, renal disease, diabetes, and chronic obstructive pulmonary disease.
Malignancy	2 (11,259)	May be associated to some extent with an increase in mortality; the magnitude of association is uncertain due to lack of adjustment for important covariates.

Risk factor	Reports (participants)	Conclusion
Pre-existing chronic conditions	2 (11,259)	Chronic obstructive pulmonary disease, diabetes, and renal disease may be associated with a large increase in mortality; these findings lacked adjustment for sex, BMI, or social factors, which may be important confounders. Other pre-existing conditions that are common among COVID-19 deaths include dementia and Alzheimer's disease, pneumonia, hypertension, ischemic heart disease, respiratory failure, renal failure, chronic lower respiratory disease, nervous system disorders, and cancer. These findings are from epidemiologic data and not adjusted for important covariates.
Special populations		
Pregnancy	1 (137,901)	Among females of childbearing age with COVID-19, pregnancy may be associated with a large-to-very large increase in hospitalization and ICU admission. The findings were not adjusted for important covariates.
Children and young adults		
Pre-existing disease in young people	1 (9,525)	Among young adults, adolescents, and children, mortality from COVID-19 may be associated with having at least one comorbidity. This finding is not adjusted for important covariates.
Pre-existing disease in infants <1 year old	1 (27)	Among a small sample of infants with COVID-19, few (20%) who were hospitalized had a comorbid condition. The findings were not adjusted for any covariates.
Age in infants <1 year old	1 (27)	There appeared to be little-to-no difference in severe outcomes by age. The findings were not adjusted for any covariates.
Sex/gender in infants <1 year old	1 (27)	Among a small sample of infants with COVID-19, half of those hospitalized were male and half were female. The findings were not adjusted for any covariates.

COVID-19=novel coronavirus disease 2019; BMI=body mass index; ICU=intensive care unit

^a Defined as "Persons, other than Aboriginal peoples, who are non-Caucasian in race or non-white in colour." Includes mainly South Asian, Chinese, Black, Filipino, Latin American, Arab, Southeast Asian, West Asian, Korean, Japanese.
