### 21 Abstract

22 The rapid spread and evolution of various strains of SARS-CoV-2, the virus responsible for 23 COVID-19, continues to challenge the disease controlling measures globally. Alarming 24 concern is, the number of second wave infections surpassed the first wave and the onset of 25 severe symptoms manifesting rapidly. In this scenario, testing of maximum population in less 26 time and minimum cost with existing diagnostic amenities is the only possible way to control 27 the spread of the virus. The previously described RNA extraction-free methods using dry 28 swab have been shown to be advantageous in these critical times by different studies. In this 29 work, we show the temporal stability and performance of the dry swab viral detection method 30 at two different temperatures. Contrived dry swabs holding serially diluted SARS-CoV-2 31 strains A2a and A3i at 25°C (room temperature; RT) and 4°C were subjected to direct RT-32 PCR and compared with standard VTM-RNA based method. The results clearly indicate that 33 dry swab method of RNA detection is as efficient as VTM-RNA-based method in both 34 strains, when checked for up to 72 hours. The lesser C<sub>T</sub> values of dry swab samples in 35 comparison to that of the VTM-RNA samples suggest better sensitivity of the method within 36 48 hours of time. The results collectively suggest that dry swab samples are stable at RT for 37 24 hours and the detection of SARS-CoV-2 RNA by RT-PCR do not show variance from 38 VTM-RNA. This extraction free, direct RT-PCR method holds phenomenal standing in the 39 present life-threatening circumstances due to SARS-CoV-2.

#### 43 Introduction

44 The life-threatening and repeated Coronavirus Disease 2019 (COVID-19) pandemic waves 45 clubbed with the emergence of new strains and scarceness of the vaccines for majority of the 46 world population, the only way out is to follow COVID-19 protocols and mass testing to stop 47 the spread of the virus. In a year's time the COVID-19 testing facilities has evolved to test 48 more samples by implementing automation and involving more skilled people. Regardless of 49 all these preparations, due to multiple waves of infection and new strains with fast spreading 50 ability, the present testing setup is unable to test the large number of samples in a time bound 51 manner. Along with this, there are multiple challenges such as shortage of Ribonucleic acid 52 (RNA) isolation reagents, samples transport facilities, equipment breakdown, and limited 53 human/financial resources (Fomsgaard & Rosenstierne, 2020). In an attempt to overcome 54 these hurdles, multiple studies attempted to present the advantages of RNA extraction-free 55 direct Reverse Transcription-Polymerase Chain Reaction (RT-PCR), without compromising 56 the sensitivity of detection (Bruce et al., 2020; Kiran et al., 2020; Padgett et al., 2020; Parikh 57 et al., 2021; Smyrlaki et al., 2020; Visseaux et al., 2021) which is being effectively 58 implemented in few countries (ICMR, 2021; Srivatsan, Heidl, et al., 2020).

59 Besides the existence of promising extraction-free RT-PCR methods, there are apprehensions 60 in implementing such methods in large scale. Those include temporal stability of the samples, 61 detection sensitivity, other logistics, and mainly the fact that diagnostic personnel being 62 accustomed to traditional methods. But the current circumstances demand more flexibility to 63 implementation of extraction-free detection methods that saves considerable time, manpower, 64 and reduce the economic burden. In this work we convincingly added more scientific 65 dimensions to the dry swab extraction-free method for Severe Acute Respiratory Syndrome-66 Coronavirus-2 (SARS-CoV-2) diagnosis that we have reported earlier (Kiran et al., 2020). 67 This work illuminates further advantages of the method and discusses the scope for 68 commercialization.

### 69 Materials and methods

### 70 Viral strains, log dilutions and swab preparation

- 71 Strains representing two different clades of SARS-CoV-2, namely A2a and A3i (GISAID ID:
- 72 EPI\_ISL\_458046; virus ID- hCoV-19/India/TG-CCMB-L1021/2020, and EPI\_ISL\_458075;
- virus ID- hCoV-19/India/TG-CCMB92 O2-P1/2020) have been reported previously and have
- been tested for the temporal stability (Gupta et al., 2021). A concentration of  $4.55 \times 10^6$  pfu/ml
- and  $8 \times 10^6$  pfu/ml viral cultures of A2a and A3i strains, respectively, were serially diluted to
- vp to 6 log folds. The swabs were immersed in different dilutions for 10-15 seconds and then
- stored as either dry swab in 15 ml sterile tubes or in 3 ml VTM-containing tubes at room
- temperature (RT;  $25\pm1\Box$ ) and 4°C for up to 3 days. Independent swabs were sampled at an
- 79 interval of 24 hours and processed as discussed below.

## 80 Sample processing

- 81 The sample processing was performed in the BSL-3 facility of CSIR-CCMB, Hyderabad,
- 82 India by following Standard Operating Procedures.
- a) Extraction of biological material from dry swabs:
- A volume of 400  $\mu$ l of TE buffer [Tris pH-7.4 10 mM, EDTA 0.1 mM] with 2mg/ml proteinase K was added and the samples were incubated at RT for 30 min to ensure the release of biological material (unless mentioned otherwise).
- b) Heat Inactivation:

The samples were than heated at 98° C for 6 min in a dry bath placed inside the laminar hood. The heat-treated samples were directly used as a template for RT-PCR.

### 90 Proteinase K concentration optimisation

Nasopharyngeal swab samples from three COVID-19 positive individuals with informed consents were collected. 400 µl of TE buffer was added to the swab samples at first and the samples were let at RT for 15 minutes. Later, four 50 µl aliquots of the samples were taken and appropriate volume of 100 mg/ml proteinase K solution was added to the aliquots, respectively, to get 2 mg/ml, 1 mg/ml, 0.5 mg/ml of proteinase K. One tube was processed without proteinase K (0 mg/ml). The samples were let at RT for another 15 minutes and were processed as described above.

### 98 **RNA extraction and RT-PCR**

99 The RNA was extracted from the VTM samples using QIAamp Viral RNA isolation kit 100 (Qiagen, Germany) by following the manufacturer's protocol. The RNA samples were 101 checked for the presence of SARS-CoV-2 RNA using FDA (Food and Drug Administration, 102 USA Government)-approved Fosun COVID-19 RT-PCR Detection Kit (Shanghai Fosun 103 Long March Medical Science Co., Ltd, China). The kit provides primers and probes for target

- 104 genes, the envelope gene (E-gene; ROX labelled), nucleocapsid gene (N-gene; JOE labelled),
- and open reading frame1ab (ORF1ab; FAM labelled) of SARS-CoV-2. The RT-PCR was
- 106 performed as per manufacturer recommendation on QuantStudio<sup>TM</sup>5. The Positive and
- 107 negative controls provided in the kit were included each time in the amplification plates, and
- 108 the  $C_T$  values were in the range of the manufacturer protocol proving to be efficient and
- 109 devoid of contamination. All the samples were tested in triplicates.

#### 110 Statistical analysis

- 111 Microsoft excel was used for statistical analysis and plotting. GraphPad prism 6 was also
- used for plotting.

#### 113 **Results**

## 114 Detection of SARS-CoV-2 RNA is independent of storage temperature till 24 hours

One of the major concerns for adopting dry swab-based diagnosis at large scale is the 115 116 stability of the viral RNA during shipping and storage. Presence of intact RNA is essential for 117 reliable diagnosis, and the integrity of RNA is dependent on multiple factors of which temperature is a crucial factor. Here, the detection of SARS-CoV-2 RNA was assessed by 118 119 subjecting contrived swabs in VTM and contrived dry swabs at two temperatures for different 120 periods of time. The results indicate that storing the contrived dry swabs at room temperature 121 (RT;  $25\pm1$  ) does not affect the detection ability for up to 24 hours. In addition, the C<sub>T</sub> 122 values of the dry swab samples and that of the RNA isolated from corresponding VTM 123 samples were comparable when stored at RT. Similarly, samples stored at  $4\Box$  showed no 124 differences when incubated in VTM and as dry swabs for 24 hours (Figure 1; Supplementary 125 File 1).

**Figure 1:** Stability of the viral RNA is unaffected by different storage conditions for up to 24 hours of storage.  $C_T$  values of the viral genes in (A) A2a strain and (B) A3i strain after 1 day of storage in the mentioned conditions. RT-PCR was carried out in triplicates for every sample and the average  $C_T$  values are plotted. Each coloured line represents one sample.

## 131 Long-term stability of the viral RNA is temperature-dependent

132 While the above results provide the stability of viral RNA unperturbed up to 24 hours at RT, 133 the long-term storage/shipping for performing genome analysis is unexplored. Therefore, we 134 studied the effect of long-term storage of the contrived samples at different temperatures. 135 Results indicated that storing the samples at  $4\Box$  could help in maintaining the integrity of 136 RNA for up to 3 days irrespective of the presence or absence of VTM. The  $C_{\rm T}$  values of the 137 VTM samples and dry swab samples stored at  $4\Box$  were comparable for majority of the 138 samples suggesting that storing the swabs in the absence of media does not affect the 139 integrity of the RNA (Figure 2; Supplementary File 1). However, when stored at RT, the dry 140 swab samples showed increased  $C_T$  indicating the loss of RNA copies after 2 days of storage. 141 As a result, samples with low viral titres went undetected. Even so, samples stored in VTM at RT, and  $4\square$  and the dry swabs stored at  $4\square$  remained intact as suggested by the C<sub>T</sub> values 142 143 that are comparable to a greater extent (Figure 2).

Figure 2: Long-term storage of dry swab samples at RT causes loss in detection of low titre samples.
CT values of the viral genes in (A) A2a strain and (B) A3i strain after 2 days of storage and similarly
that of (C) A2a strain and (D) A3i strain after 3 days of storage. RT-PCR was carried out in triplicates
for every sample and the average CT values are plotted. Each coloured line represents one sample.

148

## 150 Prolonged storage of dry swabs at 4 is as efficient as storing in VTM

151 The reduced viral RNA integrity upon storage at higher temperatures in different media has 152 been previously reported (Druce et al., 2012). To overcome this problem of reduced stability 153 the storage of samples at lower temperatures can be of probable solution. In this regard, a 154 comparison of the samples stored in different conditions revealed a temporal increase in the 155  $C_T$  values of the dry swab samples when stored at RT but not at  $4\Box$ . The median  $C_T$  values of 156 the dry swab samples stored at  $4\Box$  at all time points are comparable to that of the VTM 157 samples (Supplementary Figure 1). Statistical correlation analyses revealed that there is a 158 strong positive correlation between the  $C_T$  values of dry swab samples and VTM-RNA when 159 stored at  $4\Box$  for 3 days and at RT for 1 day (Figure 3A; Supplementary Table 1). Moreover, 160 the C<sub>T</sub> values of the dry swab samples stored at  $4\Box$  showed strong correlation between 3 days 161 and 1 day of storage (Figure 3B; Supplementary Table 2). Together, the data suggest that dry 162 swab-based sample collection could be a potential alternate for sample collection in VTM 163 given the availability of refrigeration and when the samples has to be stored or transported for 164 a longer time. Additionally, the delta  $C_{\rm T}$  values between dry swab and VTM-RNA confirms 165 the validity of the above claim, wherein the dry swab samples stored at  $4\Box$  shows negative to 166 no difference in the delta C<sub>T</sub> values when compared to VTM-RNA samples (Supplementary 167 Figure 2).

**Figure 3**: Scatter plots showing (A) the comparison of the correlation coefficients between the  $C_T$  values of the dry swab and VTM-RNA samples subjected to the given conditions and (B) the correlation between the  $C_T$  values of the dry swab samples between day 3 and day 1. RT-PCR was performed in triplicates for each sample and the average  $C_T$  values were used to calculate the correlation coefficient using.

## 175 Optimization of proteinase K concentration

176 Use of proteinase K in RNA extraction-free methods is reported to increase the detection 177 efficiency (Srivatsan, Han, et al., 2020). The FDA-authorized SalivaDirect method also uses 178 proteinase K at a concentration of 2.5 mg/ml as the major ingredient for effective detection 179 (Vogels et al., 2020). For the dry swab method using TE buffer and proteinase K, the major 180 cost component is proteinase K and finding the minimum concentration of proteinase K could 181 help in increasing the throughput of tests with a given amount of the enzyme thereby cutting 182 down the per test cost. In an attempt to optimise the concentration of proteinase K required 183 for efficient detection, we tested dry swabs from three independent COVID-19 positive 184 nasopahryngeal samples with different viral loads at four proteinase K final concentrations. 185 Results suggest that a final concentration of 0.5 mg/ml of proteinase K produces comparable 186 with that of 2 mg/ml (Figure 4). In accordance with previous reports, lack of proteinase K 187 affected the detection as suggested by increased  $C_T$  values when compared to samples with 188 proteinase K (Figure 4; Supplementary Table 3).

189 Figure 4: Line chart showing the effect of proteinase K concentration on the detection of SARS-CoV-

190 2 targets in 3 independent COVID positive individuals' samples.

#### 192 **Discussion**

193 Considering the exponential raise in the number of SARS-CoV-2 infected people and 194 hospitalisations, it is imperative to look for alternative methods to quickly diagnose and 195 control the disease spread. Based on the availability of resources and sample burden, 196 diagnostic labs need to adopt methods with faster turnover time to cater the present health 197 care demands. Here in this work, we presented an additional advantage of the dry-swab 198 method over time consuming traditional way and highlighted the elimination of cold chain 199 for shorter sample transport. The study on temporal stability of the two strains of SARS-200 CoV-2 at two different temperatures indicates that, for shorter distance transportation cold 201 chain can be avoided and the dry swab samples with low viral load also is stable at RT for 24 202 hours. In case of high sample surge the swabs can be stored at 4°C for up to 3 days without 203 compromising the detection sensitivity. The dry swab method is expected to hold similar 204 advantages in case of other emerging variants of SARS-CoV-2 as indicated by multiple 205 sewage surveillance and sequencing studies (Crits-Christoph et al., 2021; Martin et al., 2020). 206 This suggests that the virus variants could be different with respect to the rate of infection and 207 eliciting immune response, but they are generally stable for longer time in different 208 conditions. Additionally, as a measure to cut cost incurred per test, we optimised the 209 minimum final concentration of proteinase K that can produce reliable results. Our results 210 indicate that a minimum final concentration of 0.5 mg/ml of proteinase K is enough to 211 produce results comparable to that of 2 mg/ml. This evidently suggests that the throughput of 212 the tests can be increased four times in addition to bringing down the cost by four times.

213 In conclusion, the dry swab method facilitates multiple advantages at the present critical time 214 while the testing facilities are failing to cater the requirements. With the present testing 215 facilities and resources, the dry swab method can increase the throughput of a lab by three-216 folds. The challenges like reagent shortage, limited human resources and high transmission 217 rate can be handled in a better manner. The recent study on culturing virus from dry swab 218 clearly showed that virus culture can be established from dry swabs stored for days at RT in 219 TE buffer devoid of proteinase K (Ram et al., 2021). Shortly, the dry swab method conserves 220 all the advantages of gold-standard method and can deliver reliable results even faster. In the 221 present scenario, implementation of this method could provide multiple advantages in 222 containing the infection and better allocation of medical resources in the developed and 223 developing nations alike.
