ABSTRACT

Importance: More than 4 million SARS-CoV-2 infections have occurred among children and adolescents in the United States. Risk factors for SARS-CoV-2 infection among children remain poorly defined.

Objective: To evaluate the association between asthma and the risk of SARS-CoV-2 infection among children.

Design: Retrospective cohort study

Setting: A large, integrated health system in central North Carolina.

Participants: Children 5 to 17 years of age with a Durham County address and at least one health care encounter in the Duke University Health System between March 1, 2017, and February 28, 2020.

Exposure: Diagnosis of asthma

Main Outcomes and Measures: The primary outcome was SARS-CoV-2 infection identified by PCR testing of a respiratory sample collected between March 1, 2020, and October 31, 2020. We matched children with asthma 1:1 to children without asthma using propensity scores and used Poisson regression to evaluate the association between asthma and the risk of SARS-CoV-2 infection. We assessed for effect modification of this association by inhaled corticosteroid prescription and comorbid atopic diseases.

Results: Of 49,455 children, 6,515 (13%) met criteria for a diagnosis of asthma; all children with asthma were matched to a control child without asthma for a final cohort of 13,030 children. Median (interquartile range) age was 11.0 (8.0, 14.0) years, 56% were male, and 78% were non-White. A diagnosis of asthma was associated with a decreased risk of SARS-CoV-2 infection [risk ratio (RR): 0.67, 95% confidence interval (CI): 0.49-0.92]. This association tended to be stronger in children with asthma who were prescribed inhaled corticosteroids (RR: 0.60, 95% CI: 0.38-0.94) or who had comorbid atopic diseases (RR: 0.59, 95% CI: 0.39-0.88). Of the 66 children with asthma who developed SARS-CoV-2 infection, none required hospitalization for COVID-19.

Conclusions and Relevance: Children with asthma had a lower risk of SARS-CoV-2 infection, particularly children prescribed an inhaled corticosteroid or with comorbid atopic diseases. Further studies are needed to explore the complex relationship between asthma, inhaled corticosteroids, and SARS-CoV-2.

Key Points

Question: Does having asthma influence SARS-CoV-2 infection risk among children 5-17 years of age?

Findings: In this retrospective cohort study of 49,455 children, asthma was associated with a lower risk of SARS-CoV-2 infection, particularly among children with asthma who were prescribed an inhaled corticosteroid or who had comorbid atopic diseases. None of the 66 children with asthma who acquired SARS-CoV-2 required hospitalization for COVID-19.

Meaning: Children with asthma are at lower risk of SARS-CoV-2 infection and generally have mild SARS-CoV-2-associated illnesses. Use of inhaled corticosteroids and comorbid atopic diseases may contribute to the association between asthma and SARS-CoV-2 susceptibility.

INTRODUCTION

Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2), the etiological agent of coronavirus disease 2019 (COVID-19), has caused more than 185 million infections and 4 million deaths globally.¹ Current public health guidelines recommend that individuals with certain medical conditions, including moderate-severe asthma, take additional precautions to prevent SARS-CoV-2 infection.^{2,3} However, several prior studies suggested that asthma may be associated with a lower susceptibility to SARS-CoV-2 infection and a low risk of severe COVID-19. In one of the first epidemiological studies of the pandemic, only 5 of 548 (<1%) patients hospitalized at Tongji Hospital in Wuhan, China had a diagnosis of asthma.⁴ Similarly, asthmatic patients represented only 23 of 1307 (<2%) patients requiring mechanical ventilation for COVID-19 in Russia.⁵ Similar findings were reported in studies of patients hospitalized for severe COVID-19 in Saudi Arabia and Brazil.^{6,7} Additionally, in a retrospective study of 22,254 individuals tested for SARS-CoV-2 in New York City, asthma was less prevalent among individuals testing positive for SARS-CoV-2 compared to individuals testing negative for the virus (7% vs. 11%).⁸ Notably, these studies focused primarily on adults and were conducted among hospitalized patients or through convenience sampling of individuals presenting for SARS-CoV-2 testing. There is an ongoing need to investigate the association between asthma and SARS-CoV-2 infection in population-based studies of children and adolescents, among whom asthma is the most common chronic medical condition and a leading cause of hospitalization.⁹

We sought to evaluate the risk of SARS-CoV-2 infection by asthma status in a cohort of 49,455 children receiving care in a large, integrated health system in central North Carolina. We matched 6,515 children with asthma 1:1 to children without asthma using propensity scores and evaluated the association between asthma and the risk of SARS-CoV-2 infection. As a priori-specified secondary objectives, we evaluated

the extent to which use of inhaled corticosteroids (ICS) and the presence of comorbid atopic diseases modified the association between asthma and the risk of SARS-CoV-2 infection.

METHODS

Setting

This study was conducted in the Duke University Health System (DUHS), a comprehensive medical system consisting of a large academic medical center, two community hospitals, a network of primary and urgent care clinics, and both inpatient and outpatient subspecialty services. DUHS serves as the main health care provider in Durham County, North Carolina, with an estimated 85% of Durham residents receiving care within DUHS. This study was conducted during an eight-month period from March 1, 2020 to October 31, 2020.

Study Population

We identified all children 5 to 17 years of age with a Durham County address and at least one health care encounter in DUHS within the three years preceding the study period (March 1, 2017, to February 28, 2020). We classified children as having asthma if they met one of three previously validated electronic health record-based definitions during this three-year period: 1) two or more outpatient or emergency health care encounters associated with an International Classification of Diseases, Ninth/Tenth Revision (ICD-9/ICD-10) code for asthma (**Supplemental Table 1**) and an active prescription for one or more medications for asthma (**Supplemental Table 2**); 2) at least one hospital encounter associated with an ICD-9/ICD-10 for asthma and an active prescription for one of more medications for asthma; or 3) a problem list entry with an asthma-related ICD-9/ICD-10 code and an active prescription for one or more medications for asthma.¹⁰

Data Collection

We used the Duke University School of Medicine Clinical Research Datamart to abstract patient data from electronic health records.¹¹ Data recorded included age, gender, race/ethnicity, insurance status, and the neighborhood deprivation index, a metric that incorporates income, education, employment, and housing quality to create scores for neighborhoods based on socioeconomic disadvantage.¹² To account for differences in health system engagement that could influence the likelihood of being tested for SARS-CoV-2 infection, we recorded if the child's pediatrician was within DUHS, if the child had a well-child visit in the two years prior to the study period, and the number of health care encounters in the one year preceding the study period. To identify a subset of children with asthma who were more likely to have an atopic asthma phenotype, we identified allergic rhinitis, atopic dermatitis, food allergies, and other comorbid atopic diseases using ICD-9/ICD-10 codes (**Supplemental Table 1**). SARS-CoV-2 infection was identified based on positive PCR testing of a respiratory sample obtained for clinical care.

Statistical Analysis

We described characteristics of the study population by asthma status, by performance of SARS-COV-2 testing, and based upon the results of SARS-CoV-2 testing. We used Poisson regression with a sandwich variance estimator to evaluate associations between asthma, demographics, insurance type, health system engagement, and neighborhood characteristics with performance of SARS-CoV-2 testing.¹³ We used a similar modeling approach to evaluate associations between these same factors and positive testing for SARS-CoV-2 among children who underwent one or more tests for the virus. We used logistic regression to evaluate associations between demographics, insurance type, health system engagement, and neighborhood characteristics with asthma status. The predicted covariate values from this model were then used to generate propensity scores for the probability of having asthma for all children in the dataset. We then matched each child with asthma to a single child without asthma using nearest-neighbor matching of propensity scores. Distributions of propensity scores were evaluated for balance across the

asthma and control groups (**Supplemental Figure 1**). For our primary analysis, we used Poisson regression with a sandwich variance estimator to evaluate the association between asthma status and the risk of SARS-CoV-2 infection in the propensity score-matched cohort. Finally, in a priori-specified secondary analyses, we fit modified Poisson regression models to evaluate for effect modification of the association between asthma status and SARS-CoV-2 infection by ICS prescription and comorbid atopic diseases in the propensity score-matched cohort. All statistical analyses were performed using R version 4.0.2.¹⁴

RESULTS

Patient characteristics

Of 49,455 children, 6,515 (13.2%) met the definition for asthma (**Figure 1**). Characteristics of the unmatched cohort by asthma status are shown in **Table 1**. Compared to children without asthma, children with asthma were more likely to be male (58% vs. 50%, $p<0.001$), to identify as non-Hispanic Black race (55% vs. 33%, $p<0.001$), and to have public insurance (57% vs. 48%, $p<0.001$). Children with asthma were also more likely to have had a well-child visit within the prior two years (69% vs. 52%, $p<0.001$), had more health care encounters in the preceding one year [median (interquartile range (IQR)): 2 (1, 4) vs. 1 (0, 2), $p<0.001$], and were more likely to have a primary care physician in DUHS (99% vs. 97%, $p<0.001$). Age and neighborhood deprivation were similar among children with and without asthma.

Factors associated with SARS-CoV-2 testing

Overall, 3,594 (7.3%) children had one or more tests for SARS-CoV-2 during the study period. Children with asthma were more likely to have been tested for SARS-CoV-2 infection than children without asthma (10.4% vs. 6.8%, $p<0.001$). Patient age, race/ethnicity, insurance status, and neighborhood deprivation index scores differed by SARS-CoV-2 testing status (**Table 2**). Specifically, non-Hispanic

Black race and self-pay insurance status were associated with a lower risk of being tested for SARS-CoV-2, while higher risks of being tested were observed for Hispanic ethnicity, public insurance, and higher neighborhood deprivation index scores, corresponding to higher deprivation and lower neighborhood socioeconomic status. We also observed higher levels of previous health system engagement among children who were tested for SARS-CoV-2. Compared to children who were not tested for SARS-CoV-2, tested children were more likely to have had a well-child visit in the two years preceding the study period, had more health care encounters in the year preceding the study period, and were more likely to have a primary care physician in DUHS. A total of 564 (1.1%) children tested positive for SARS-CoV-2 infection during the study period, including 66 (1.0%) children with asthma and 498 (1.2%) children without asthma. Among children tested for SARS-CoV-2 infection, non-White race, public and self-pay insurance, and higher neighborhood deprivation were associated with positive testing for SARS-CoV-2 infection (**Table 3**). One child without asthma required hospitalization for COVID-19.

Association between asthma and SARS-CoV-2 infection

We next generated propensity scores for the probability of having asthma for all children and matched each of the 6,515 children with asthma to a child without asthma using nearest-neighbor matching of propensity scores. Propensity score matching resulted in a population that was closely matched on patient characteristics (**Table 1**). Median (IQR) age was 11.0 (8.0, 14.0) years, 56% were male, and 78% were non-White. In this propensity score-matched cohort, 164 (13%) children tested positive for SARS-CoV-2 infection during the study period, including 66 (9.8%) children with asthma and 98 (16.0%) children without asthma (**Table 4**). Asthma was associated with a decreased risk of SARS-CoV-2 infection [risk ratio (RR): 0.67, 95% confidence interval (CI): 0.49–0.92]. Additionally, we found evidence of effect modification of this association by prescription of ICS and comorbid atopic disease. Specifically, children with asthma who were prescribed ICS had a lower risk of SARS-CoV-2 infection than matched control children without asthma (RR: 0.60, 95% CI: 0.38–0.94), but this association was not significant among

children with asthma who were not prescribed ICS (RR: 0.75, 95% CI: 0.49–1.15). Similarly, compared to matched control children without asthma, the risk of SARS-CoV-2 infection was lower among children with asthma and comorbid atopic diseases (RR: 0.59, 95% CI: 0.39–0.88), but not among children with asthma who did not have these conditions (RR: 0.83, 95% CI: 0.51–1.35).

DISCUSSION

In this population-based study of nearly 50,000 children in central North Carolina, asthma was associated with a lower risk of acquiring SARS-CoV-2 infection. This association tended to be stronger among children with comorbid atopic diseases or concomitant ICS prescription, suggesting that these factors may contribute to the reduced susceptibility of this population to SARS-CoV-2. We identified marked differences in the likelihood of children being tested for SARS-CoV-2 by sociodemographic factors. Finally, we found no evidence that asthma predisposes children to severe COVID-19.

Few prior studies evaluated the association between asthma and susceptibility to SARS-CoV-2 infection. In a nationwide cohort study of 219,959 adults in South Korea, adults with asthma had a slightly higher risk of testing positive for SARS-CoV-2 compared with a propensity score-matched comparison group without asthma (2.3% vs. 2.2%, respectively).¹⁵ In a retrospective evaluation of electronic health record data from 7,256 children tested for SARS-CoV-2 in a pediatric healthcare network in the United States, 87 of 424 (21%) children who tested positive for SARS-CoV-2 had a diagnosis of asthma, in keeping with the asthma prevalence among children in this network.¹⁶ Moreover, in a study of 135,794 patients less than 25 years of age who underwent SARS-CoV-2 testing in seven pediatric health networks in the United States, children with asthma and other previously diagnosed respiratory conditions had a lower SARS-CoV-2 positivity rate.¹⁷ Finally, in a community-based cohort study of 382 children and adolescents with a documented SARS-CoV-2 exposure in central North Carolina, children with asthma

were less likely to acquire the virus.¹⁸ In the current study, we found that asthma was associated with a 35% lower risk of SARS-CoV-2 infection among children after accounting for differences in SARS-CoV-2 testing practices. Our findings can be used by parents, educators, and health care providers to inform decisions surrounding precautions and treatments for children with asthma.

ICS are among the medications most commonly prescribed to children with asthma.^{19,20} Though previous research suggests that ICS use increases the risk of non-COVID-19 respiratory tract infections, the available data indicate that these medications may not increase susceptibility to and severity of SARS-CoV-2 infection.²¹ Use of ICS for pre-existing respiratory diseases was not associated with COVID-19 severity in a study of more than 8 million adults in the United Kingdom.²² Similarly, among adults in South Korea, use of ICS was not associated with COVID-19 risk and mortality.²³ In contrast, in the OpenSAFELY Study, adults with asthma who were prescribed high-dose ICS, but not low- or medium-dose ICS, had a higher risk of death from COVID-19.²⁴ Finally, a retrospective analysis of 928 adult patients did not identify an association between ICS use and the likelihood of testing positive for SARS-CoV-2.²⁵ Our findings suggest that ICS use may contribute to the lower risk of SARS-CoV-2 infection among children with asthma and emphasize the importance of continuing these medications during the ongoing COVID-19 pandemic.

Prior epidemiological studies have failed to demonstrate an association between asthma and COVID-19 severity. In studies conducted in adult populations, asthma has generally not been identified as a risk factor for COVID-19 severity and mortality.^{5,26-31} Similarly, studies of children hospitalized for COVID-19 have not identified a consistent association between asthma and COVID-19 severity. Among 222 children and adolescents hospitalized with COVID-19 in the United States, 13.5% had a prior diagnosis of asthma – only slightly higher than the estimated national prevalence of asthma among children (8-10%).³² In a study of 177 children with SARS-CoV-2 infection in the Washington, D.C. metro area, asthma was

not more common among children admitted to the hospital than among non-hospitalized children.^{33,34} Similarly, in a study of 46 children hospitalized for SARS-CoV-2 infection in New York, asthma was not associated with a requirement for intensive care.³⁵ Finally, an electronic health record-based analysis of children undergoing SARS-CoV-2 testing at Children's Hospital of Philadelphia facilities found that asthma was associated with a lower odds of hospitalization for COVID-19.³⁶ In our cohort, none of the children and adolescents with asthma who were diagnosed with SARS-CoV-2 infection required hospitalization for COVID-19. Taken together, these data suggest that asthma is not associated with worse outcomes among children and adolescents with SARS-CoV-2 infection.

There are several potential mechanisms by which asthma may reduce the SARS-CoV-2 infection risk. SARS-CoV-2 entry is mediated by the cell surface proteins angiotensin-converting enzyme 2 (ACE2) and transmembrane protease serine 2 (TMPRSS2), both of which have been demonstrated to be expressed at lower levels in individuals with asthma compared to those without asthma, though the data are conflicting regarding the levels of ACE2 and TMPRSS2 expression associated with different asthma endotypes.³⁷⁻⁴¹ Atopic asthma is a common endotype among children and adolescents, and is associated with excessive T-helper type-2 (Th2) responses,^{42,43} which have been associated with lower expression of ACE2 and TMPRSS2.^{44,45} Previous research also suggested potential mechanisms by which ICS could influence SARS-CoV-2 susceptibility. In a study of adults with chronic obstructive pulmonary disease, treatment with ICS was associated with reduced ACE2 expression, and this effect appeared to be mediated through suppression of type I interferon.⁴⁶ Further, the ICS ciclesonide has been shown to dampen host inflammatory responses and reduce *in vitro* replication of SARS-CoV-2 and other human coronaviruses.⁴⁷ Finally, the risk of SARS-CoV-2 infection might be lower among children and adolescents because of differences in behavior and risk mitigation strategies. In particular, children with asthma and other chronic respiratory diseases could have less exposure to SARS-CoV-2 than children without these chronic

conditions because of differences in perceived risk of severe COVID-19 and infection prevention or shielding practices.

The availability of SARS-CoV-2 testing to children during the COVID-19 pandemic has been influenced by national and local policies, testing availability, and our evolving understanding of the virus. Thus, the factors influencing the likelihood of being tested for SARS-CoV-2 have important implications for understanding the epidemiology of the virus and for identifying barriers to accessing health services. We found that children who identified as Hispanic ethnicity were tested at a higher rate than white children and children from other racial minority groups, but Hispanic children still had a far higher test positivity rate (32%) than other groups, highlighting the extent to which the Latinx community has been disproportionately affected by the COVID-19 pandemic in central North Carolina. We also observed that individuals with disadvantaged living conditions were tested at a higher rate and had a higher test positivity rate than individuals who lived in neighborhoods with higher socioeconomic status. Consistent with this finding, a study of children presenting for drive-up testing at an academic medical center reported that families in the highest income quartile based on census block group estimates tested positive at a lower rate than those from lower income quartiles.⁴⁸ Children with public insurance were both more likely to be tested for SARS-CoV-2 and had a higher SARS-CoV-2 positivity rate than children with private insurance. Taken together, these findings highlight significant disparities in SARS-CoV-2 testing accessibility and disease burden among children in central North Carolina by race/ethnicity and socioeconomic status.

Our study has several strengths and limitations. First, our cohort included more than 6,000 children with a current asthma diagnosis and active prescriptions for controller medications. While this stringent definition enabled us to have substantial confidence in the diagnosis in children classified as having asthma, children with mild asthma or who did not have active prescriptions for controller medications

were likely misclassified as not having asthma. We relied upon SARS-CoV-2 test results from within the health care system, and therefore could not account for SARS-CoV-2 testing that may have been performed at other sites. To minimize this possibility, we focused on children who reside in Durham County, for which DUHS provides the vast majority of primary and specialty pediatric services. We assumed that children who were not tested for SARS-CoV-2 did not have the virus; due to limited testing availability and asymptomatic infections, it is likely that some SARS-CoV-2 infections were not identified. We used propensity score matching to account for confounding in demographics associated with asthma and SARS-CoV-2. Finally, we were unable to account for differences in infection prevention and shielding behaviors that may have existed between asthmatic children and children without asthma.

In summary, despite the continued general precaution regarding asthma and COVID-19, we found no evidence that asthma predisposes children to SARS-CoV-2 infection or severe illness from COVID-19. We strongly recommend that children with asthma continue their treatment and asthma action plans during the ongoing COVID-19 pandemic, especially if these plans include ICS. Further research is needed to evaluate the complex relationships that exist between asthma, ICS, and SARS-CoV-2.

6-10	294	54%	934	32%	1.29	(1.08 – 1.54)
Well-child visit in the prior two years	350	62%	2,091	69%	1.12	(0.94 – 1.33)
Median (IQR) number of encounters in prior year	3	(2, 5)	4	(2, 8)	0.95	(0.93 – 0.97)
Primary care physician in DUHS	561	>99%	3,020	>99%	1.23	(0.47 – 4.97)

CI, confidence interval; IQR, interquartile range; DUHS, Duke University Health System

Table 4. Associations between asthma status and SARS-CoV-2 infection, propensity score-matched cohort

		SARS-CoV-2 Infection		Adjusted RR (95% CI)		P
Primary analysis						
Asthma (n=6,515)		66	9.8%	0.67	(0.49, 0.92)	0.01
No asthma (n=6,515)		98	16.0%	1.00	Ref	–
Effect modification analyses						
Inhaled corticosteroid prescription						
	Yes (n=3,384)	30	8.3%	0.60	(0.38, 0.94)	0.03
	No (n=3,131)	36	11.5%	0.75	(0.49, 1.15)	0.19
Comorbid atopic disease						
	Yes (n=4,003)	37	8.0%	0.59	(0.39, 0.88)	0.01
	No (n=2,512)	29	13.5%	0.83	(0.51, 1.35)	0.45

Supplemental Table 1. Diagnostic codes for asthma and atopic diseases

Diagnosis	ICD-9	ICD-10
Asthma	493.*	J45.*
Atopic diseases		
Allergic rhinitis	477.*	J30.*
Acute atopic conjunctivitis	372.05	H10.1*
Other chronic allergic conjunctivitis	372.14	H10.45
Personal history of allergy, other than to medicinal agents, presenting hazards to health	V15.0*	Z91.0*
Anaphylactic reaction due to unspecified food	995.6*	T78.*
Other adverse food reactions, not elsewhere classified	995.7	T78.*
Atopic dermatitis and related conditions	691.*	L20.*

Supplemental Table 2. Asthma prescription medications

Category	Medication
Rescue medications	Albuterol Dry Powder Inhaler [ProAir]
	Albuterol Inhalant Solution
	Albuterol Metered Dose Inhaler [ProAir, Proventil, Ventolin]
	Albuterol Oral Tablet
	Albuterol/ipratropium bromide Inhalant Solution [DuoNeb]
	Albuterol/ipratropium bromide Metered Dose Inhaler [Combivent]
	Ipratropium bromide Inhalant Solution [Atrovent]
	Ipratropium bromide Metered Dose Inhaler [Atrovent]
	Levalbuterol Inhalant Solution [Xopenex]
	Levalbuterol Metered Dose Inhaler [Xopenex]
ICS	Beclomethasone Dipropionate Metered Dose Inhaler [Qvar]
	Budesonide Dry Powder Inhaler [Pulmicort]
	Budesonide Inhalant Solution [Pulmicort]
	Ciclesonide Metered Dose Inhaler [Alvesco]
	Fluticasone furoate Dry Powder Inhaler [Arnuity Ellipta]
	Fluticasone propionate Dry Powder Inhaler [Flovent]
	Fluticasone propionate Metered Dose Inhaler [Flovent]
Mometasone furoate Dry Powder Inhaler [Asmanex]	
LTRA	Montelukast Oral Tablet [Singulair]
	Zileuton Oral Tablet [Zyflo]
LABA	Salmeterol inhalant product [Serevent]
LAMA	Tiotropium Metered Dose Inhaler [Spiriva]
Combination therapies	Budesonide / formoterol fumarate Metered Dose Inhaler [Symbicort]
	Fluticasone furoate / vilanterol Dry Powder Inhaler [Breo]
	Fluticasone propionate / salmeterol Metered Dose Inhaler [Advair]
	Fluticasone propionate / salmeterol Dry Powder Inhaler [Advair]
	Mometasone fumarate / formoterol fumarate Metered Dose Inhaler [Dulera]
Biologics	Omalizumab [Xolair]
	Mepolizumab [Nucala]

LTRA, leukotriene receptor antagonist; LABA, long-acting beta agonist; LAMA, long-acting muscarinic agent

Supplemental Figure 1. Distribution of propensity scores in matched cohort
