21 Abstract

22 **Objectives:** Australia’s public health restrictions (‘lockdown’) in 2020 successfully contained the spread of
23 COVID-19. These included a national ‘initial’ lockdown (March-May), and ‘ongoing’ lockdown (July-
24 November) for metropolitan Victorian residents only. Australia’s experience offers an opportunity to assess
25 impacts of lockdown on families with children, in the relative absence of disease morbidity and mortality. This
26 study (1) described the experience of initial lockdown and (2) evaluated the impact of ongoing lockdown, on
27 family finances and mental health.

28 **Methods:** Data were drawn from the June and September 2020 Royal Children’s Hospital National Child Health
29 Polls. Caregivers of children from the states of Victoria and New South Wales reported on job/income loss;
30 material deprivation (inability to pay for essential items); income-poverty; mental health (Kessler-6); impact on
31 caregiver/child mental health; and caregiver/child coping. Data from N=1207/902 caregivers in June/September
32 were analyzed; Aim (1) with weighted descriptives; Aim (2) with Difference-in-Difference adjusted linear
33 regression models (New South Wales provided the comparator).

34 **Results:** Following initial lockdown, one-quarter of families reported job/income loss; one-third reported material
35 deprivation. Negative impacts on mental health were reported for half the caregivers and one-third of children.
36 Few caregivers or children had difficulties coping. During Victoria’s ongoing lockdown, job/income loss
37 increased by 11% (95%CI: 3-18%); Kessler-6 poor mental health by 6% (95%CI: 0.3-12%) and negative mental
38 health impacts by 12% for caregivers (95%CI: 6-23%) and 14% for children (95%CI: 4-20%). Female (versus
39 male) caregivers, metropolitan (versus regional/rural) families, and families with elementary school-aged children
40 (versus pre-/high-school) were most affected.

41 **Conclusions:** Ongoing lockdown had negative impacts on mental health, employment, and income, but not
42 deprivation or poverty, likely because of the government income supplements introduced early in the pandemic.
43 Balancing the benefits and harms of lockdown requires planned responses to outbreaks, and evidence-informed
44 financial and mental health supports.

45

46 **Introduction**

47 The coronavirus SARS-COV-2 (COVID-19) was first identified in Australia in late January 2020. From March
48 2020 onwards, Australian governments at the federal and state levels implemented a range of public health
49 restrictions. These included stay-at-home orders, which are also known as 'lockdown'. At the time, Australia's
50 response was among the most stringent internationally.(1) By 31 December 2020, the measures successfully
51 contained infection to an overall incidence rate of 111 cases and 3.5 deaths per 100,000 people.(2) In contrast,
52 other high-income countries with more lenient public health restrictions, such as the United States (US) and
53 United Kingdom (UK), recorded rates of 5895 and 3730 cases per 100,000 people, respectively.(2) Reviews of
54 previous pandemics and the data emerging from COVID-19 show how quarantine and isolation can harm
55 household finances and individuals' mental health.(3-9) This is particularly the case for families with children,
56 where there are mixed views on the balance of harms versus benefits of lockdown.(6, 10-12) Unlike many high-
57 income countries, Australia's low incidence of COVID-19 makes it possible to examine the effects of lockdown
58 mostly independent of the compounding disease impacts. We aimed to contribute to this evidence base using
59 nationally-representative survey data collected from Australian families in June and September 2020.

60 The evolution of Australia's COVID-19 public health restrictions is presented in S1 Fig. From 23 March to 1 June
61 2020, the national 'initial' lockdown included mandatory quarantine for returned travelers; travel bans; self-
62 isolation for suspected/confirmed cases; stay-at-home orders; and closure of schools and 'non-essential'
63 businesses.(13, 14) Five weeks after initial lockdown eased, a second wave of infections in the state of Victoria
64 rapidly surpassed active cases in the first wave, with the national peak reaching 721 new cases (2.8 per 100,000)
65 in 24 hours. From 8 July-23 November 2020, Victorian residents entered an 'ongoing' and more severe lockdown.
66 The public health measures were strictest for metropolitan areas (in the state's capital city of Melbourne)
67 compared with regional and rural Victoria. Previous lockdown measures were reinstated, the stay-at-home orders
68 were further restricted, a night-time curfew was added, and early childhood education and care providers closed

69 (see S1 Fig.). Compliance with Australia’s lockdown measures was driven by state enforcement, through police
70 surveillance and fines.

71 To protect against the economic fallout of lockdown, the Australian federal government rapidly implemented a
72 suite of short-term financial supports.(15, 16) Shown in S1 Fig., they included an unemployment supplement
73 (‘JobSeeker’) which doubled recipients’ social welfare benefits from \$550 to \$1,100 a fortnight;(15) a wage
74 supplement for eligible businesses to retain their workforce (‘JobKeeper’);(16) allowing early access to
75 superannuation;(17) and free childcare for working families.(18) Banks and creditors also allowed loan
76 repayments to be deferred for up to 10 months. These social policy changes represent some of the largest (albeit
77 temporary) in Australia’s history. Indeed the JobKeeper and JobSeeker supplements were so significant that, by
78 September 2020, levels of poverty and housing stress in Australia were substantially lower than the levels directly
79 preceding COVID-19.(15)

80 While these social policies buffered Australians from poverty, global data emerging on COVID-19 show that
81 lockdown has substantial and negative impacts on household finances and mental health. A cohort of over 70,000
82 UK adults surveyed from March to August 2020 found that anxiety and depression symptoms were highest in the
83 first weeks of lockdown, and worse for women and young adults.(19) An Australian cross-sectional survey of
84 1200 adults repeated weekly from March 2020 found similar patterns for self-reported financial stress and
85 material deprivation (unable to afford essential items).(20) The same survey data showed that mental distress
86 tripled for parents from 8% pre-COVID-19 to 24% during the pandemic.(20) While children have been less
87 affected by COVID-19 morbidity and mortality,(21, 22) they are more developmentally vulnerable to their
88 socioeconomic environment than adults.(23, 24) Previous studies show that the stress and isolation of lockdown
89 can negatively impact children’s mental health for many months,(25) and school closures can compromise
90 children’s educational opportunities for years.(6, 10)

91 To our knowledge, no studies have investigated the impact of COVID-19 lockdown on both the financial and
92 mental health experiences of families with children, in the relative absence of disease morbidity and mortality.

93 This evidence can inform economic and population health responses to the current pandemic as well as future
94 crises. This study uses the natural experiment that occurred in Australia, whereby the state of Victoria experienced
95 ongoing and more severe lockdown, to address this evidence gap. Data are drawn from the Royal Children’s
96 Hospital (RCH) National Child Health Poll, the only nationally representative survey to measure COVID-19
97 impacts for caregivers with children aged 0-17 years. The Poll was conducted in June (when the initial lockdown
98 had ended for all Australians) and in September 2020 (when only metropolitan Victorians were in ongoing,
99 stricter lockdown). Data from the neighboring state of New South Wales (NSW), which experienced only the
100 initial lockdown, provide the comparator. The two states are inherently similar in terms of their population, size,
101 and geographic location.

102 The specific study aims were to (1) describe families’ financial and mental health experiences directly after the
103 initial lockdown and (2) evaluate the impact of ongoing lockdown on family finances and mental health (a)
104 overall and (b) by caregiver gender (female versus male), child age (0-4, 5-12 and 13-17 years), and metropolitan
105 (versus regional/rural) location. We hypothesized that the ongoing lockdown would be associated with increased
106 financial hardship and worse mental health. We anticipated that these impacts would be worse for female
107 caregivers and for metropolitan families.

108

109 **Methods**

110 **Design:** The RCH National Child Health Poll is conducted by the Royal Children’s Hospital in Melbourne,
111 Australia. It collects periodic, cross-sectional surveys of nationally representative samples of approximately 2000
112 Australian caregivers of children aged 0-17 years. Each survey explores a current or emerging public health issue
113 of national relevance to child health. The process for selecting Poll topics is responsive to and informed by
114 population health needs and the nation’s social agenda. Research themes and questions are chosen via review of
115 the scientific and grey literature in consultation with multidisciplinary experts across the country. Surveys are

116 administered in English equivalent to a sixth-grade (elementary school) level. Surveys reported in this paper were
117 conducted during 15-23 June and 15-29 September 2020 with two different samples and focused on families’
118 experience of financial hardship and mental health 3 and 6 months into the COVID-19 pandemic. The Royal
119 Children’s Hospital Human Research Ethics Committee approved the research (HREC 35254). After the Polls
120 were conducted, we realized the opportunity to investigate the impact of ongoing lockdown relative to initial
121 lockdown on families’ financial and mental health experiences.

122 **Sampling frame and data collection methods:** The surveys were conducted using web-based survey technology
123 provided by the private vendor, Online Research Unit (ORU), under contract to the RCH. ORU has an established
124 research panel of more than 200,000 Australian residents, with approximately 30% caring for a child in the target
125 range (less than 18 years of age). Recruitment involves offline and online methods to select a nationally
126 representative distribution by jurisdiction, caregiver gender and age. Panel members have a unique identifying
127 number that means they can only access and complete the Poll once. Only one person per household can join the
128 panel. To be eligible for the RCH Poll, panel members must have internet access to complete the online surveys.
129 They must be living in Australia and aged 18 years or older. The field period for each Poll is approximately two
130 weeks. Respondents are remunerated for their participation with points that can be exchanged for department store
131 gift vouchers. All responses are anonymous.

132 **Measures:** Both Polls analyzed in this study captured demographic information including caregiver and child age
133 and gender, number of children in care, caring for a child with additional health needs (chronic illness, health
134 condition, disability), partner status, Healthcare Card status (identifies low-income), caregiver education level,
135 Aboriginal or Torres Strait Islander status, country of birth, language spoken at home, living in
136 metropolitan/regional/rural areas and postcode. Family finances were assessed using:

- 137 1. Nine items adapted from the CoRonavIruS Health Impact Survey (CRISIS) caregiver version (26): “What
138 changes in employment or income have occurred in your household due to coronavirus/COVID-19?”
139 (response options “yes” versus “no”) including: “job loss by one caregiver”; “job loss by two caregivers”,

140 “difficulty paying bills or for necessities”, “working longer hours”, “filing for unemployment”; “applying for
141 Government assistance”; “reduced work hours”; “reduced total household income” or “none of the above”. A
142 binary variable describing any job loss (by one or two caregivers) or reduction in income due to COVID-19
143 (versus not) was created to enable comparison with other Australian studies, e.g. (27)

144 2. Eight items adapted from the Household, Income and Labour Dynamics in Australia (HILDA) Survey Wave
145 18 Household Questionnaire Material Deprivation Module (28) asking “In the last month, because of money
146 pressure did you miss or put off” (response options: “yes” versus “no”): mortgage or rent repayments;
147 electricity, gas, water bills; food; healthcare; prescription medicines; home or car insurance; mobile phone
148 bills; and internet. Two summary variables were created: (a) a binary “any material deprivation” variable
149 identifying inability to pay for one or more essential items (versus “none”), and (b) a “total material
150 deprivation count” summing the number of essential items where payment was missed or put off (possible
151 range 0-8).

152 3. Current total household income before tax, categorized into 10 options ranging from “less than \$500 p/week”
153 to “more than \$3,000 p/week”, plus “prefer not to say”. A binary variable was created to summarize low
154 income (“less than AU\$1,000 p/week” versus more) based on Australian thresholds for HealthCare Card
155 eligibility and definitions of income-poverty.(29)

156 Mental health was assessed using:

157 4. 6 items of the Kessler-6 (K6) assessing caregivers’ self-reported anxiety and depressive symptoms
158 encountered in the last 4 weeks. Scored on a 5-point Likert scale from 1 “none of the time” to 5 “all of the
159 time”. Summarized into (a) a continuous total score, and (b) a binary variable indicating “poor mental health”
160 (total score 19 or more) versus not (total score 6-18).(30)

161 5. A 5-point item adapted from UK Young Minds Matter 31) describing the impact of COVID-19 on mental
162 health, dichotomized into negative (“small negative/large negative”) versus positive (“none/small
163 positive/large positive”). Reported by caregivers for (a) themselves and (b) each child.

164 6. A 4-point study-designed item reported by caregivers and dichotomized into “struggling or not coping” versus
165 “coping or thriving”. Reported by caregivers for (a) themselves and (b) each child.

166 **Analysis methods:**

167 **Data preparation:** Families living in the Australian states of Victoria and NSW were retained in the analytic
168 sample. For each family, we assigned data from the Australian Bureau of Statistics Socio-Economic Indexes for
169 Areas (SEIFA) Index of Relative Disadvantage, a national area level index derived from census data for all
170 individuals living in a postcode, with higher scores indicating greater advantage. To create a consistent analytic
171 sample, the 41 families (comprising 63 children) who preferred not to report their country of birth, and the 1
172 family (comprising 2 children) without SEIFA, were excluded (see S2 Fig.). To reduce the effects of non-
173 response and non-coverage, all demographics, financial hardship, and mental health experiences were weighted
174 using national demographic distributions for gender, state/territory, and SEIFA, as per the most recent Australian
175 Bureau of Statistics data.

176 **Analysis:** Demographics, family finances and mental health (Aim 1) were described using proportions for
177 categorical data and mean and standard deviation (SD) for continuous data. The change in family finances and
178 mental health as related to lockdown (Aim 2a) was estimated using Difference-in-Difference analyses
179 implemented as an interaction term between time (September versus June) and treatment group dummy variables
180 (Victoria versus NSW) using linear regression models. The Difference-in-Difference approach is appropriate
181 given our aim (to examine potential causal impacts) and because of the policy set-up. The ongoing lockdown was
182 introduced only for Victoria and not for NSW. This created a natural experiment that allowed comparison of a
183 group of families who were affected by ongoing lockdown (Victoria) with an unaffected group (NSW). The
184 Difference-in-Difference estimator compares families’ outcomes before and after the policy implementation.
185 The Difference-in-Difference models were run unadjusted and adjusted for all potential confounding variables
186 available in the dataset: child and caregiver age and gender (male/female; noting no other genders were reported);
187 number of children; child with additional health needs (versus not); one-caregiver family (versus not); owns a

188 Health Care Card (versus not); caregiver education (<Year 10/Year 10/Year 12/trade or apprenticeship/certificate
189 or diploma/undergraduate/postgraduate); Aboriginal or Torres Strait Islander (versus not); caregiver born outside
190 of Australia (versus in Australia); Home language other than English (versus speaks English at home); lives
191 regionally or rurally (versus metropolitan); and SEIFA quintile. Caregiver mental health (total K6 score) and
192 effects of family cluster were accounted for in all child models using robust estimation. These models were
193 repeated for three subgroups (Aim 2b): (i) caregiver gender (female/male); (ii) child age (grouped at 0-4 years
194 (preschool), 5-12 years (elementary school), 13-17 years (secondary/high school); (iii) and
195 metropolitan/regional/rural location as a proxy for severity of lockdown, noting that metropolitan Victorians
196 endured a more severe and longer lockdown than their regional and rural counterparts but also that the whole state
197 was affected. Subgroup models were adjusted for the same variables except the grouping variable, which provided
198 the strata for analysis.

199 We chose to run linear regression models as interpretation is simpler than logistic regression and most of the
200 predicted y-values were bounded within 0-1. To check the robustness of these models, we ran marginal effects
201 probit models for the dichotomous outcomes for the whole sample (not presented), which confirmed the linear
202 regression output. For all models, the adjusted analyses are presented as the main results (unadjusted analyses are
203 not included). As 293 caregivers preferred not to disclose their income, these analyses should be interpreted with
204 caution. Data were analyzed with Stata v13.

205

206 **Results**

207 **Sample characteristics:** S2 Fig. presents the respondent flowchart for the analytic sample. In June, after the
208 initial lockdown ended, 2697 Australian caregivers were invited and 2020 (75%) completed the Poll. Of these,
209 1207 caregivers (604 Vic, 603 NSW) with 1992 children (985 Vic, 1008 NSW) were included in the analysis. In
210 September, during Victoria's ongoing lockdown, 1769 caregivers were invited and 1434 (81%) completed the

211 Poll. Of these, 902 caregivers (460 Vic, 442 NSW) with 1584 children (786 Vic, 798 NSW) were included in the
212 analysis.

213 Table 1 presents the weighted estimates for participant characteristics. Caregivers were an average of 40 years
214 old, and three in five respondents were female. Each caregiver looked after an average of two children, and two in
215 five cared for children with additional needs. One in five caregivers had a Health Care Card (an indicator of low
216 income) and one-quarter were sole caregivers. One-quarter of respondents were born outside of Australia, and a
217 similar proportion spoke a language other than English at home. One in six identified as living in regional or rural
218 areas, compared with metropolitan capital cities. Ninety-five percent of respondents had completed high school
219 (compared with around 85% nationally)(32) and less than 1% identified as Aboriginal or Torres Strait Islander
220 (compared with 3% nationally).(33)

221 **Experiences after initial lockdown (Aim 1):** Table 2 and S1 Table describe families' financial and mental health
222 experiences in June 2020, and Table 3 presents the adjusted mean differences (MDs) between NSW and Victoria
223 ('Vic June' column). Twenty-nine percent of NSW caregivers reported job or income loss due to the COVID-19
224 pandemic, compared with 24% of Victorians (MD=5%; 95% CI: 0.1 to 10%). Tables 2-3 show that financial and
225 mental health experiences were otherwise similar between states in June. Fifteen percent of families reported low
226 income, and 30% reported material deprivation (unable to pay for essential items including mortgage or rent;
227 electricity, gas, water bills; food; healthcare; prescription medicines; home or car insurance; mobile phone bills;
228 and internet). Caregivers averaged one missed payment out of the eight essential items. One in five caregivers
229 reported poor mental health according to the K6; half said the pandemic negatively impacted their mental health;
230 and one-third said their child's mental health was negatively impacted. Thirteen percent of caregivers and 10% of
231 children were struggling or not coping.

232
233

Table 1. Demographic characteristics (weighted) of New South Wales and Victorian families surveyed after initial lockdown (June 2020) and during Victoria’s ongoing lockdown (September 2020) in proportions (95% confidence intervals) unless specified.

Demographic characteristics	New South Wales		Victoria	
	June	September	June	September
Caregiver	N=603	N=442	N=604	N=460
Age (years), mean (CI)	40.7 (39.9 – 41.5)	40.1 (39.3 – 40.9)	40.1 (39.4 – 40.8)	40.2 (39.5 – 41.0)
Female	57.4 (51.5 – 63.0)	61.5 (55.6 – 67.0)	57.0 (51.3 – 62.5)	57.8 (51.6 – 63.8)
Number of children in care, mean (CI)	1.8 (1.7 – 1.9)	1.9 (1.8 – 1.9)	1.8 (1.7 – 1.9)	1.8 (1.8 – 1.9)
Caregiver to child with additional health needs ^a	41.8 (36.0 – 47.8)	47.2 (41.2 – 53.3)	34.7 (29.5 – 40.3)	43.2 (37.0 – 49.6)
One-parent family	28.5 (23.0 – 34.7)	20.2 (15.7 – 25.6)	24.5 (19.5 – 30.1)	14.4 (10.5 – 19.4)
Health Care Card (identifies low income)	18.3 (13.8 – 24.0)	20.9 (16.3 – 26.3)	17.5 (13.4 – 22.5)	17.7 (13.3 – 23.0)
Education				
Less than Year 10	0.9 (0.3 – 2.2)	1.2 (0.5 – 3.2)	0.5 (0.1 – 1.8)	1.2 (0.4 – 3.1)
Year 10	4.6 (2.7 – 7.9)	6.3 (3.9 – 9.9)	3.2 (1.4 – 7.1)	1.2 (0.5 – 2.6)
Year 12	8.9 (6.2 – 12.7)	11.1 (7.6 – 16.1)	12.9 (9.6 – 17.1)	11.5 (8.4 – 15.7)
Trade / apprenticeship	4.8 (2.7 – 8.5)	4.8 (3.0 – 7.5)	2.4 (1.1 – 4.9)	2.9 (1.4 – 6.0)
Certificate / diploma	21.1 (17.1 – 25.7)	24.2 (19.3 – 29.8)	23.4 (18.1 – 30.5)	20.1 (15.5 – 25.6)
Undergraduate	39.0 (33.6 – 44.6)	32.6 (27.2 – 38.6)	37.8 (32.4 – 43.5)	43.3 (37.2 – 49.7)
Postgraduate	19.6 (15.9 – 24.0)	19.8 (15.6 – 24.8)	21.1 (16.3 – 26.8)	19.8 (15.0 – 25.8)
Aboriginal or Torres Strait Islander	0.2 (0.1 – 0.5)	0.3 (0.2 – 0.4)	0.2 (0.06 – 0.4)	0.3 (0.1 – 0.5)
Born in Australia	77.2 (72.6 – 81.2)	80.7 (75.8 – 84.7)	72.1 (66.5 – 77.1)	77.4 (71.9 – 82.1)
Home language other than English	22.1 (18.0 – 26.7)	31.1 (25.6 – 37.1)	27.0 (22.0 – 32.8)	20.2 (15.7 – 25.7)
Lives regionally or rurally (versus metropolitan)	18.8 (14.0 – 24.8)	12.8 (9.2 – 17.6)	20.1 (15.8 – 25.2)	14.2 (10.4 – 19.1)
SEIFA Index of Social Disadvantage Quintile				
1 (most disadvantage)	19.4 (14.7 – 25.1)	23.4 (18.1 – 29.8)	15.2 (11.0 – 20.7)	17.1 (12.5 – 23.0)
2	24.3 (18.7 – 30.8)	19.7 (15.4 – 24.9)	28.4 (22.8 – 34.7)	23.6 (18.6 – 29.4)
3	18.7 (14.9 – 23.2)	22.5 (17.7 – 28.3)	20.5 (16.5 – 25.2)	20.7 (15.3 – 27.3)
4	15.0 (11.8 – 18.9)	11.5 (8.5 – 15.4)	18.7 (15.2 – 22.6)	20.5 (16.3 – 25.5)
5 (least disadvantage)	22.6 (18.9 – 26.8)	22.8 (18.8 – 27.4)	17.3 (14.3 – 20.7)	18.1 (14.5 – 22.3)
Child	N=1008	N=798	N=984	N=786
Age (years), mean (CI)	9.6 (9.2 - 10.1)	8.6 (8.2 - 9.1)	8.9 (8.5 – 9.3)	8.8 (8.3 - 9.3)
Female	49.2 (44.9 – 53.6)	49.6 (45.0 – 54.1)	49.6 (45.2 – 54.0)	49.0 (44.3 – 53.7)

234 CI: 95% Confidence Interval. SEIFA: Socio-Economic Indexes for Areas. Data weighted using national demographic distributions for gender, state, and
 235 SEIFA.

236 ^a Examples of additional health needs include asthma, epilepsy, and diabetes; of disability includes hearing impairment, intellectual disability, and autism

237

238 **Table 2. Financial and mental health experiences (weighted) of New South Wales and Victorian families surveyed after initial lockdown (June**
 239 **2020) and during Victoria’s ongoing lockdown (September 2020) in proportions (95% confidence intervals) unless specified.**

Financial and mental health experiences	New South Wales		Victoria	
	June	September	June	September
1. Job or income loss due to COVID-19 ^a	28.5 (23.3 – 34.3)	25.2 (20.5 – 30.6)	23.6 (19.0 – 29.0)	35.1 (29.0 – 41.7)
2a. Any material deprivation: unable to pay for essential items ^b	31.2 (26.0 – 37.0)	30.4 (25.0 – 36.3)	29.5 (24.5 – 35.0)	25.9 (20.6 – 31.9)
2b. Total material deprivation count ^b mean, (CI)	1.10 (0.85 - 1.34)	1.23 (0.92 - 1.53)	1.12 (0.86 – 1.38)	0.93 (0.70 – 1.17)
3. Low household income (<AU\$1000 p/w) ^c	14.7 (10.4 – 20.4)	21.5 (15.2 – 26.0)	15.2 (11.3 – 20.1)	21.5 (16.0 – 28.3)
4a. Caregiver mental health (K6 total score), mean (CI)	12.9 (12.1 – 13.6)	12.9 (12.2 – 13.8)	12.9 (12.2 – 13.5)	13.6 (12.8 – 14.4)
4b. Caregiver poor mental health (K6 cut-point) ^d	20.6 (15.6 – 26.8)	16.6 (12.3 – 22.1)	17.3 (13.0 – 22.5)	22.2 (17.1 – 28.4)
5a. Negative impact of COVID-19 on caregiver mental health	50.2 (44.3 – 56.1)	49.8 (43.9 – 55.9)	48.3 (42.6 – 54.1)	58.6 (52.3 – 64.6)
5b. Negative impact of COVID-19 on child mental health	32.1 (27.0 – 37.8)	39.2 (33.3 – 45.4)	30.8 (26.0 – 36.1)	47.6 (41.3 – 54.0)
6a. Caregiver struggling or not coping ^e	11.4 (8.3 – 15.4)	16.3 (12.1 – 21.5)	13.7 (9.9 – 18.6)	19.2 (14.6 – 24.7)
6b. Child struggling or not coping ^e	10.2 (7.2 – 14.2)	14.5 (10.4 – 19.7)	8.7 (5.7 – 13.3)	14.2 (10.4 – 19.0)

240 K6: Kessler-6, SEIFA: Socio-Economic Indexes for Areas Index of Relative Disadvantage. Data weighted using national demographic distributions for
 241 gender, state, and SEIFA.

242 ^a Job loss by one or two adults, or reduction in income, due to COVID-19.

243 ^b Any one or more of mortgage or rent; electricity, gas, water bills; food; healthcare; prescription medicines; home or car insurance; mobile phone bills;
 244 internet.

245 ^c Missing 293 caregivers who preferred not to report income.

246 ^d K6 dichotomized into a binary “poor mental health” (total score 19 or more) versus not (total score 6-18).

247 ^e Versus “coping/thriving” categories.

248 **The impact of ongoing lockdown (Aim 2):** Fig. 1 and Table 3 present the fully-adjusted Difference-in-
249 Difference linear regression analyses testing the impact of ongoing lockdown on families' finances and mental
250 health. Over the June-September 2020 period, relative to their NSW counterparts, Victorians reported an 11%
251 increase in job or income loss (95% CI: 3 to 18%). There was no evidence that ongoing lockdown was related to a
252 change in material deprivation or the proportion of households reporting low income. Ongoing lockdown was
253 associated with a 0.83 point increase (95% CI: -0.08 to 1.74) in the K6 total score and a 6% increase (95% CI: 0.3
254 to 12%) in the binary K6 measure of poor mental health. The negative impact of the COVID-19 pandemic on
255 mental health was also exacerbated by ongoing lockdown, affecting 14% (95% CI: 6 to 23%) more Victorian
256 caregivers and 12% (95% CI: 4 to 20%) more children relative to their NSW counterparts.

257 **Fig. 1. Adjusted mean Difference-in-Difference estimates (%) of the impact of ongoing lockdown on**
258 **families' finances and mental health (all binary), overall and by subgroups, data drawn from Table 3**

259 Fig. 1 and Table 3 present the adjusted Difference-in-Difference analyses for the subgroups of caregiver gender
260 (female/male); child age (0-4 (pre-school), 5-12 (elementary school), 13-17 years (secondary/high-school)); and
261 location (metropolitan/regional-rural). The evidence for a negative impact of ongoing lockdown on job/income
262 loss and caregiver mental health was strongest for female caregivers, caregivers of elementary-school aged
263 children, and caregivers living in metropolitan areas. Notably, Table 3 ('NSW September' column) shows that the
264 differences between initial and ongoing lockdowns in measures of job/income loss and K6 mental health were in
265 part due to worsening outcomes for Victorians as well as improving outcomes for NSW families. The proportion
266 of NSW caregivers reporting job/income loss decreased by 6% (95% CI: 0.2-11%) from June to September. The
267 same reduction was evident in the poor mental health (K6) of female caregivers (mean difference=6%, 95% CI:
268 0.3 to 12%). There was evidence that ongoing lockdown exacerbated the negative impact of the pandemic on
269 children's mental health, for all subgroups except for families living in regional/rural areas. There was no
270 evidence of a relationship between ongoing lockdown and whether the caregiver or their children were coping or
271 not, for the cohort overall or by subgroups.

272
273

Table 3. Adjusted Difference-in-Difference linear regression models estimating the impact of ongoing lockdown on families' finances and mental health for the Total sample and by subgroups, using New South Wales (NSW) families in June 2020 as reference group.

288 ^e Versus “coping/thriving” categories.

289 Discussion

290 This study investigated the impacts of COVID-19 lockdown on family finances and mental health in the context
291 of Australia's minimal disease burden. In June 2020, after an initial national lockdown from March-May, a
292 quarter of Australian caregivers of children aged 0-17 years reported job or income loss due to the pandemic. One
293 in three reported material deprivation (being unable to afford essential items such as housing, food, amenities, or
294 healthcare). One in five caregivers reported poor mental health; half said that the first three months of the
295 pandemic had negatively impacted their mental health; and a third reported the same negative impact for their
296 children. By September 2020, Victoria's ongoing lockdown from July onwards was associated with increased job
297 and income loss, and negative mental health impacts for caregivers and children, compared with neighboring
298 NSW. There was no evidence that ongoing lockdown affected families' experiences of material deprivation or
299 income poverty. As anticipated, the evidence for the negative impacts of lockdown were strongest for female
300 caregivers and families living in metropolitan Victoria. While the negative impacts of ongoing lockdown affected
301 families across children's ages, they were most pronounced for families with children of elementary school
302 compared with preschool or high school ages.

303 Although the RCH Poll does not have pre-pandemic data for comparison, the financial and mental health impacts
304 reported by the June cohort are consistent with national data. In April, the Australian Bureau of Statistics
305 estimated that 2.7 million Australians (almost 20% of the working population) lost their jobs or hours of
306 work.(34) The Australian Temperament Project survey of 498 families from March-September 2020,(27) and the
307 right@home trial survey of 319 mothers from May-December 2020 (unpublished), reported job/income losses of
308 24% and 27% respectively, using the same questions as our study. The third of families reporting material
309 deprivation is equivalent to pre-pandemic data from the Longitudinal Study of Australian Children.(35) In our
310 study, one in five families reported poor mental health in June 2020 according to the K6. This aligns with the
311 Australian 'Pulse of the Nation' survey in which 24% of parents reported mental distress across the first months
312 of lockdown. Despite the global differences between countries' infection rates and governments' approaches to

313 public health restrictions, there are commonalities in the mental health data emerging from the pandemic.(36-39)

314 The Born in Bradford study found that 19% and 16% of mothers reported clinically-significant levels of

315 depression and anxiety, respectively, during the first lockdown in UK (April-June 2020).(40) In a nationally

316 weighted survey from the US in June, 27% of parents said their mental health had declined during the

317 pandemic.(41)

318 Given the negative economic and psychosocial impacts of lockdown,(36-41) it follows that ongoing lockdown

319 was associated with increased job and income loss, and poor mental health. Our findings of a larger negative

320 impact on the mental health of female versus male caregivers is consistent with similar findings from the

321 aforementioned ‘Pulse’ data.(20) That families with elementary school-aged children were most affected is likely

322 due to the stress and disruption of home-schooling in July-September. More supervision is required for children in

323 elementary school than high school, and balancing home schooling with usual paid or unpaid work was a

324 substantial challenge for families.(42) Finally, metropolitan Victorians experienced stricter and ongoing lockdown

325 than their regional and rural counterparts. This explains the findings of increased job/income loss and greater

326 negative impacts on caregiver and child mental health for this subgroup, relative to their NSW counterparts.

327 Our findings for children are like other studies investigating the lockdown experiences of young people. Analysis

328 by the Australian Human Rights Commission in the earliest months of the pandemic found that increased

329 numbers of older children reported first time mental health challenges or concerns of self-harm.(43) The COVID-

330 19 Unmasked Study which surveyed Australian families with young children (aged 1-5 years) also found that

331 Victorian caregivers exposed to ongoing lockdown reported increasing mental health symptoms for themselves

332 and their children.(44) Interestingly, in the Unmasked study, young children living outside of Victoria (exposed to

333 only the initial lockdown) were still experiencing higher than average levels of anxiety symptoms by the time of

334 Victoria’s ongoing lockdown. We found a similar pattern in our study. For the NSW families exposed to initial

335 lockdown only, caregivers reported improved mental health for themselves by September but not for their

336 children.

337 This study has several strengths. It builds on existing COVID-19 research to show the specific impacts of ongoing
338 lockdown on families in the relative absence of the virus, i.e., isolating the toll that widespread mortality has on
339 mental health. The RCH Poll is the only nationally-representative survey of Australian families with children to
340 assess financial and mental health impacts of COVID-19. It comprised large cross-sectional and nationally
341 representative surveys, which employed strong methodology (surveys piloted and included the validated K6);
342 collected data on caregiver and child mental health; surveyed female and male caregivers; and achieved good
343 response rates. In other Polls, indicators (frequency/prevalence) across a range of topics are almost universally
344 consistent with more traditionally-obtained estimates, providing support for the sample selection and survey
345 administration methods. The Difference-in-Difference modeling is well-established method of analyzing policy
346 change (in our case, lockdown law differences). The natural experiment allowed us to gauge causal relationships
347 by simulating a counterfactual; that is, what would have happened in the absence of a second lockdown.

348 There were also limitations. The Poll only samples adults who are 18 years and older, so younger caregivers are
349 missing. As a subgroup who experience more adversity, this means results may be conservative. Measures were
350 caregiver-reported, by only one caregiver in the household. Ideally, information would be collected from all
351 caregivers and children directly. A significant proportion of caregivers did not report family income, and the
352 sample sizes for preschool-aged children and regional/rural subgroup analyses were small, limiting power for
353 detecting differences. There were also limitations to the analyses. The common trends' assumption of Difference-
354 in-Difference estimation supposes that the untreated units (NSW in September) provide the appropriate
355 counterfactual of the trend that the treated units would have followed if they had not been treated. However, our
356 results are defensible because the time between the first and second surveys was short (4 months); thus,
357 minimizing potential differential trends across NSW and VIC. We also controlled for all available and potentially
358 confounding socioeconomic and demographic variables in the analyses.

359 This work extends the existing evidence base by trying to understand the specific impacts of ongoing lockdown in
360 the context of minimal disease burden. Based on our findings, we offer three considerations for pandemic
361 response and recovery planning. First, while job and income loss increased with ongoing lockdown, this did not

362 translate to increased material deprivation or income poverty. This finding provides support for the effectiveness
363 of the Australian government's extraordinary income supplements, introduced early in the pandemic to offset the
364 anticipated economic fallout of lockdown. This interpretation is supported by modeling demonstrating the
365 substantial reductions in Australia's poverty levels resulting from these social policies.(15) Given that the income
366 supplements offered were temporary, the fundamental need for financial security must be considered when
367 enacting future lockdown measures in response to further outbreaks.

368 Second, for families who were unexposed to ongoing lockdown, there was some recovery in employment/income
369 and female caregivers' mental health. Population-level data for UK adults demonstrated a similar pattern of
370 improved mental health after the initial sharp decline resulting from lockdown.(19) This suggests that many
371 caregivers can recover from the negative impacts of lockdown, provided they have effective financial buffers (and
372 presumably that the public health restrictions are also effective). While the Poll data were limited, they did not
373 suggest a recovery for children. It is important that children's experiences and needs are prioritized during
374 response and recovery planning so that any persistent negative impacts are adequately redressed.(45, 46)

375 Third, the negative financial and mental health impacts of ongoing lockdown were substantial, and
376 disproportionately affected families with elementary school-aged children, and female caregivers. In a country
377 such as Australia, which has encountered relatively little viral impact, the negative impacts of lockdown,
378 especially for school-aged children and female caregivers, may outweigh the direct impact of the disease itself.
379 While this study was underpowered to investigate the experience of families living in lower socioeconomic
380 environments, the evidence suggests that inequity is likely to be exacerbated and entrenched by the social and
381 economic disruption of COVID-19.(27, 46, 47) Ongoing follow-up of cohorts is necessary to understand if and
382 how caregivers and children recover from lockdown, and how best to support the population groups who are most
383 adversely affected. Balancing the benefits and harms of lockdown requires planned responses to future outbreaks,
384 and evidence-informed financial and mental health supports.
