Can 10x cheaper, rapid air filtration control the pandemic?

Devabhaktuni Srikrishna, Patient Knowhow, Inc.

sri.devabhaktuni@gmail.com, www.patientknowhow.com

Abstract: Public health departments such as CDC and California Department of Public Health (CA-DPH) advise HEPA-purifiers to limit transmission of SARS-CoV-2 in classrooms and community spaces. CA-DPH recommends 4-6 air exchanges per hour often necessitating multiple HEPA-purifiers per room, unaffordable in under-resourced community settings. Pressure to seek cheap, rapid air filtration resulted in proliferation of lower-cost, Do-It-Yourself (DIY) air purifiers whose performance is not well characterized compared to HEPA-purifiers. Primary metrics are clean air delivery rate (CADR), noise generated (dBA), and affordability ($$). CADR measurement often requires hard-to-replicate laboratory experiments with generated aerosols. In this study, we use simplified, low-cost measurement tools of ambient aerosols enabling scalable evaluation of aerosol filtration efficiencies (0.3 to 10 microns), estimated CADR, and noise generation to compare a dozen HEPA-purifiers and DIY purifier designs. DIY purifiers consist of one or two box fans coupled to single MERV 13-16 filters (1"-5" thick) or quad filters in a cube. Accounting for reduced filtration efficiency (%) of MERV 13-16 filters (versus HEPA) at the most penetrating particle size of 0.3 microns, estimated CADR of DIY purifiers using 2" (67%), 4" (66%), and 5" (85%) filters at lowest fan speed was 293 cfm ($35), 322 cfm ($58), and 405 cfm ($120) comparable to best-in-class, low-noise generating HEPA-purifier running at maximum speed with at 282 cfm ($549). Quad filter designs, popularly known as Corsi-Rosenthal box, achieved gains in estimated CADR less than 80% over single filter designs, less than the 100% gain by adding a second DIY purifier. Replacing one of the four filters with a second fan resulted in gains of 125%-150% in estimated CADR. DIY alternatives using single filters compare favorably to HEPA-purifiers in estimated CADR, noise generated at five to ten times lower cost, enabling cheap, rapid aerosol removal around the world.

Conflicts of Interest

I have no relevant interests to declare. I am not associated with any of the manufacturers

mentioned in this research.

Introduction

Recent studies demonstrate live SARS-Cov-2 in micron[1][2] and submicron[3] aerosols from the

exhaled breath of infected people. Pathogen-carrying aerosols have potential to accumulate in

airspaces of poorly ventilated, indoor spaces such as classrooms, clinics, offices, homes,

restaurants, and bars and other community settings, and if inhaled may result in COVID-19

infections.[4] Separately, toxic aerosol pollution such as from wildfires, wood burning, and

other sources can be encountered in these same locations with ventilation using unfiltered,

outdoor air. Portable air filtration in the form of commercially available, high efficiency

particulate air purifiers (HEPA-purifiers) is useful to remove both types of aerosols without

relying on centralized air-handling systems designed to turn on / off to control temperature,

not necessarily to run continuously to sanitize the air.

Indoor ventilation upgrades, HEPA-purifiers, and respirators that can remove SARS-Cov-2

particles and its variants, other airborne viruses causing natural or artificial pandemics,

aerosolized bacteria such as anthrax, and particulate pollution can be expensive or difficult

causing many organizations or households to hesitate.[71] To meet or exceed 4 to 6 air

exchanges per hour (ACH) recommended[58] by California Department of Public Health or

exceeding 15 ACH used in passenger aircraft, high price-points for select HEPA-purifier

models without incurring excessive noise generation make them unaffordable for many

households and communities.

For example, in a typical classroom (30'x30'x8'), a HEPA-purifier with clean air delivery rate

(CADR) of 300 cubic feet per minute (cfm) needs 24 minutes to cycle the air once (2.5 air

exchanges per hour or ACH) under ideal mixing conditions.[5][6] This classroom would require

2-3 air HEPA-purifiers with low-noise generation costing $400-$500 each (with periodic

$40-$80 filter replacements) to achieve 4-6 ACH costing approximately $1000-$1500 per

classroom, outside the budget of many schools. Getting 15 ACH as in hospitals and passenger

aircraft would require proportionally more HEPA-purifiers putting it further out of reach.

Figure 1: Classroom dimensions (length x width x height)

Lower cost alternatives to HEPA-purifiers in use for a decade were investigated for both their air filtration properties and safety. A Minimum Efficiency Rating Value-13 (MERV-13) filter attached to a box fan (e.g. using duct tape, bungee cord, rubber band, clips) was demonstrated to effectively filter wildfire PM2.5 and submicron particles.[7] Ford Motor Company sponsored "Scrappy Filtration" which donated 20,000 box-fan and air filters held together with a cardboard structure for use in classrooms to underserved communities.[8][9] However, lower-cost box-fan-filter alternatives have not yet been directly compared using the same test methods to HEPA-purifiers along key metrics: filtration efficiency (%), air flow and clean air delivery rate (CADR), and noise generation (dBA).

Below, we compare cost-effectiveness of aerosol filtration by best-in-class, portable HEPA-purifiers and do-it-yourself (DIY) alternatives built from box fans and HVAC filters rated at MERV-13, 14, 15 and 16. Comparison is based on three metrics: estimated clean air delivery rate (CADR), the noise generated (dBA), and initial cost or affordability ($). Measurement devices include an ISO-certified, calibrated aerosol meter for input/output particle filtration

of sizes ranging from 0.3 μm to 10 μm, airspeed meter to measure airflow, and NIOSH sound

meter app to measure noise. Leveraging these test methods, we were able to evaluate and

compare three HEPA-purifiers, 6 single-filter and three 3 (quad and triple filter)

configurations with box fans without conducting twelve different aerosol-generating

experiments. We also evaluate DIY configurations involving quad filter design in a cube

formation, popularly known on social media as the Corsi-Rosenthal box, proposed to enhance

airflow and CADR over a single filter design, and compare this to a cube design replacing

one of the four filters with an additional fan.

Safety Notes: California Air Resource Board recommends never leaving box-fan air filters

unattended while turned on, and to use box fans in the US those manufactured after 2012

because they have a fused plug to prevent electrical fires e.g. if the device is inadvertently

knocked over.[10] Chemical Insights, a subsidiary of Underwriter Laboratories, recently tested

five different electric box fan models (approximately 20" × 20" in size) with attached air

filters and concluded that all measured temperatures fell below the maximum acceptable

thresholds defined by the market safety standard for electric fans (UL 507).[11] The resources

Methods

Traditional methods that measure the effect of the air purifier (and its CADR) using the decay

rate of aerosols generated or injected into an isolated, unoccupied room require greater

investment of time, effort, risk of inhalation of the generated aerosols, and training/expertise

compared to the much simpler DIY test methods described here.[78][79] We use ambient aerosols

to rapidly compare different filters, fans, and configurations with low-cost, measurement

tools available online (e.g. Amazon) also making these results easy to replicate and verify

with limited resources.

HEPA-purifiers. Three models evaluated include the Coway Airmega 300 ($549, 285 cfm),

Coway AP-1512HH ($229, 233 cfm), and Airthereal AHG550 ($233, 324 cfm). Unit prices

are as listed on Amazon and "smoke" clean air delivery rate (CADR) in units of cubic feet

per minute (cfm) is as listed on manufacturer website.

HVAC filters with box fan. For DIY configurations, the box fans used are 20" Lasko Fan

($20) along with 20" x 20" HVAC filters made by Nordic Pure of width and rating 1"

MERV-14 ($11), 2" MERV-13 ($15), and 4" MERV-14 ($38), 4" MERV-15 ($42), by 3M of

width and rating 1" MERV 14 ($26), and by Lennox of width and rating 5" MERV-16 ($99).

MERV stands for minimum efficiency reporting values. The single and quad filter designs

pictured in Figure 2 use one fan, and the triple filter design uses two fans with one fan

replacing one of the filters. The square-shaped 20" box fans tend to pull in air from their front

at their corners of the box[80][81], and a cardboard shroud of 14" diameter was attached to the

output side (front) of each fan to concentrates and enhance airflow through the filter. For

comparison, two methods of attaching the box fan to the air filters included vacuum (no

attachment just relying on airflow), duct tape, and velcro. Unit prices are as listed on Home

Depot, Amazon, or Walmart.

Figure 2: Do-It-Yourself Box Fan and Filters (single, quad filter designs with one fan

and triple filter design with two fans)

Aerosol filtration efficiency. For each HEPA-purifier or box fan filter, counts at each

particle size (0.3, 0.5, 0.7, 1.0, 2.5, 5, and 10 µm) were tested using an ISO-certified, particle

counter (Temtop Particle Counter PMD 331 available on Amazon) with the filter turned 'on'

and 'off' consecutively. The tests were conducted near an open window with fan blowing air

through the window to allow for aerosols (particles) from outdoors to continuously enter the

room. The particle counter is calibrated to within 10% at each particle size by the

manufacturer. Five counts were recorded and averaged on the particle counter when its input

was placed directly at the output of the air purifier/filter for 30 seconds. The filtration

efficiency at each particle size was estimated by the formula, efficiency = 1 - on / off. To

compare each fan-filter configuration in this study, the filtration efficiency depends only on

the ratio of on to off, not on their absolute values.

Figure 3: Aerosol particle counter

125
126

128   **Air flow.** For each HEPA-purifier or DIY box fan filter, the airspeed was measured using an

129   anemometer (BTMETER BT-100 Handheld Anemometer available on Amazon) held at the

130   output perpendicular to the airflow. An average of three or more airspeed measurements (feet

131   per minute) were multiplied by area of output to estimate the airflow (cubic feet per minute).

132   **Figure 4: Anemometer**

133
134

135   **Noise.** Noise measurements were taken for each air purifier/filter using an iPhone app

136   maintained by National Institute for Occupational Safety and Health (NIOSH).[12] Three or

137   more noise measurements were taken at a 9" distance perpendicular to the direction of the

138   output airflow and averaged.

Figure 5: NIOSH sound level meter (app)

Results

Note: Measurements in each table below are shown as averages (standard deviation in

brackets).

HEPA-purifiers. As shown in Table 1, the results for the HEPA-purifiers show particle

filtration efficiencies near or exceeding 95% at most particle sizes ranging from 0.3 to 10 μm

and higher in many cases. At their maximum fan speed (3), the noise generated by the Coway

Airmega 300 was lowest and most (subjectively) tolerable of the three models. To achieve

similar subjective tolerability levels both the Coway AP-1512 and the Airthereal AGH550

had to be set at fan speed 2 which cut their estimated airflow (CADR) roughly in half. As a

verification of the estimation methodology, the estimated airflow (cfm) using the anemometer

was reasonably close to the smoke CADR rating from the manufacturer's website.

Table 1: Performance of HEPA-purifiers

Setup		Noise and Airflow			Filtration Efficiency (%) avg of five measurements at each particle size (µm)						
	Price (est.)	Fan speed	Noise (dBA) avg. of three samples 9" away	Est. Airflow (output) cfm	0.3	0.5	0.7	1.0	2.5	5.0	10.0
Coway Airmega 300	$549	3	59.3 (2.1)	282 (61)	94.1 (0.9)	94.5 (1.1)	97.0 (0.96)	97.4 (0.92)	98.3 (1.5)	98.3 (1.8)	98.0 (1.6)
Coway AP-1512	$229	3	64.7 (0.57)	223 (3.7)	97.4 (0.3)	98.1 (0.4)	98.5 (0.6)	98.7 (0.8)	98.4 (1.7)	98.0 (3.0)	97.6 (5.5)

Airthereal AGH550	$233	2	47.3 ± 1.5	206 (42)							

Single filter configurations with box fan. The noise generated by the box fan was

(subjectively) tolerable only at fan speed #1 (out of three) with a measured noise level of 54

dBA comparable to the Coway Airmega 300 at 59 dBA. As shown in Table 2, the filtration

efficiency of the MERV-13, 14, 15, or 16 filters at the most penetrating particle size of 0.3

µm varied by thickness from approximately 60% to 85% with highest observed for MERV-

16 filter and lowest for the MERV 13 filter, well below the HEPA filters. Even though

MERV-13 filters may remove less than 80% of particles in just one pass, if the air

recirculates multiple times through filter the aerosol concentrations can be rapidly reduced.[7]

The filtration efficiency exceeded 90% in some cases at particle sizes above 1 µm.

For all filters, filtration efficiencies were measured at fan speed #3, but also at fan speed #1

for the 2" MERV 13 and 1" MERV 14 filters at which the filtration efficiencies were higher.

169 In general, that is expected to hold true with the other filters so the estimated CADR for each

170 filter at fan speed #1 (above) would be commensurately higher as well.

171 **Table 2: Performance of single-filter configurations with a box fan**

												)

Cube configurations with box fan(s). Using comparably rated filters and fan speeds, the

quad filter design with one box fan (4x1), popularly known as the Corsi-Rosenthal box,

showed significant improvement in airflow and filtration efficiency over single filters (Table

3). Whereas results from attaching the filters were similar with duct tape (to seal up any gaps)

or velcro (leaving small airgaps), suggesting any leaks created by a loose fit may not make

much difference. Notably, the filtration efficiency of the quad filter design was marginally

better than the corresponding single filter design possibly due to lower pressure across the

filters. The three extra filters in the CR box (4x1) increased airflow by less than 50% over

equivalently rated single filter configuration (1x1), whereas it took adding an extra fan and

two extra filters in the cube formation (3x2) to double the airflow and estimated CADR.

183

Discussion

Accounting for reduced filtration efficiency of MERV-13,14,16 filters at the most penetrating

particle size of 0.3 μm compared to HEPA, the estimated clean air delivery rate (CADR) of a

do-it-yourself (DIY) setup using 2" MERV-13 (67%), 4" MERV-14 (66%), 5" MERV 16

(85%) filters with a box fan running at fan speed 1 for tolerable noise was 293 cfm, 322 cfm,

405 cfm. This is comparable or better than a best-in-class, low-noise generating HEPA-

purifier running at maximum speed with at 282 cfm. Yet the upfront cost of the components

of the DIY setup were approximately 5 to 10 times less ($35-$58-$120) than best-in-class

HEPA-purifiers ($549).

Figure 6: Estimated CADR (cfm) for DIY Air Purifiers (filters x fans) @ speed #1

196
197
At least two studies have measured the CADR of cube configurations (popularly known as

the Corsi-Rosenthal box or CR box) by observing the decay rates of generated aerosols. The

first study is by UC-Davis[78] measured 600 cfm at lowest fan speed to 850 cfm at highest fan

speed. The second study is by Illinois Institute of Technology[79] (IIT), measured below 300

cfm in the range of 0.5 to 3 µm (dust) at the highest fan speed but above 450 cfm in the range

of 5-11 µm (pollen). Both used five 2" MERV-13 filters (instead of four in our study) of

similar dimensions so it is unclear why they differ by a factor of two. Our results were in

between these two studies but more consistent with the UC-Davis study. The estimated

CADR of cube configurations with four 2" MERV 13 filters was 471 cfm at lowest fan speed

1 and 659 cfm at the highest fan speed 3 using 73% filtration efficiency at 0.3 µm (most

penetrating particle size). It is quite possible that greater filtration efficiencies at larger

particle sizes may account for this difference with UC-Davis results which is based on

generated salt aerosols. It is also possible differences may be accounted for by number of

filters (4 vs 5), fans, and other differences in estimation methodology but further

investigation would be required to fully understand why there is such a range.

However at all fan speeds the quad filter design, CR box, did not achieve gains in CADR of

more than 80% over a single filter design which is in contrast to the 200-250% gains also

reported by UC-Davis (also with shroud and 20" Lasko box fan),[13] separate from the UC-

Davis study in the prior paragraph. CR boxes are unlikely to exceed the airflow with no

filters. At fan speed 1, the airflow of quad 1" MERV 14 filter design (546 cfm) was within

25% of that with no filters (646 cfm), and the airflow of the single 1" MERV 14 (381 cfm)

was within 50% of no filters. This suggests the quad 1" design is close to optimal but cannot

be improved by a factor of 200% over the single 1" filter. At fan speed 1, the airflow with no

filter (646 cfm) was measured to be 70% more than the airflow with a single 1" filter (381

cfm), 47% more than 2" MERV-13 filter (437 cfm), and only 32% more than the 4" MERV-

14 filter (488 cfm). The cost and extra setup effort from the quad filters (CR box) can be

alternatively expended on more simply replicating a new box fan filter (+ 100% gain) so that

the airflow is then distributed to different locations in the room or classroom. To illustrate

this, replacing one of the 2" MERV-13 filters in the quad filter configuration with a second

fan resulted in gains of approximately 125%-150% in estimated CADR (at fan speeds 1 and

3) which is notably better than 100% possibly due to improved filtration efficiency.

Regardless, our results suggest a sweet spot between speed of setup, simplicity, size, and cost

is a single 20" box fan with 2" MERV-13 ($35), 4" MERV-14 filter ($58) of 20" length and

width. Single filter is easier and simpler to setup than multi-filter designs which is an

advantage for scaling up DIY approaches. Alternatively, if higher filtration efficiency is

desired a 5" MERV-16 filter can be used ($120). Given the simplicity and low-cost of the

box-fan design using single 2" or 4" MERV-13/14 filters, form-factor improvements at a

marginal cost may include a more stable, cardboard box frame so it is not so easy to knock

over with printed designs to make it aesthetically pleasing. An aluminum mosquito screen

fixed to the shroud in front of the fan can help keep small objects (e.g. fingers or pencils)

from contacting the fan blade which may be especially important for classroom[70] and home

applications when young children are present.

Limitations

The filtration efficiencies and airflow results for box fan used a certain set of filters and fans

made by certain manufacturers, but they vary widely among different manufacturers of

comparably rated MERV 13, 14, 15, 16 filters. Hence filter selection is critical to achieving

the results desired. There may also be variability in filter performance due to manufacturing

defects or variations among fans and filters from the same manufacturer. The long-term

durability of filtration efficiency and airflow of these filters after extended use with box fans

is also uncharacterized unlike HEPA-purifiers which have well-understood operational

history.

If aerosol transmission is largely eliminated would it bring the pandemic under control?

Table 4 summarizes divergent views of public health agencies and academics on the

transmission modes of SARS-Cov-2. Large-scale, real-world evidence of transmission events

aboard passenger airplanes (inflight) may help settle this debate in favor aerosols playing a

potentially more important role in inter-household, superspreading of SARS-Cov-2 than other

transmission modes. Prior to mandatory mask usage on passenger flights, inflight

transmission was observationally confirmed with genomic sequencing[27][28][29] and some have

credited institution of mandatory masking for reduction in mass transmission

(superspreading) aboard flights[30][31] which appears to validate the utility of droplet

precautions[32] to reduce transmission within a short distance (e.g. 6 feet). However, even prior

to mandatory masking aboard aircraft expert opinion has been that there were relatively few

published documented superspreading (mass-transmission) events.[31][33][34][35]

Table 4: Divergent Views on Transmission Modes of SARS-Cov-2.

The Aerosol-Droplet-Fomite Debate	Observational studies and expert opinion observe superspreading events are responsible for most SARS-Cov-2 transmission, and approximately 80% of cases are transmitted by 10% to 20% of the infected (super spreaders)[1 14 15] and if so controlling superspreading can potentially control the pandemic. Numerous superspreading events in community settings have been attributed to aerosol inhalation[9] although, conversely, confusion persists about what is the most important transmission mode (for superspreading): aerosol (airborne), droplet, or surface (fomite). Theoretically at least, superspreading of SARS-Cov-2 without aerosols (e.g. droplet deposition onto mucous membranes, direct contact with an infected person or indirectly via surfaces or fomites) cannot be ruled out because superspreading is also observed with viruses thought to be spread primarily by direct physical contact such as ebola. During the West African Ebola epidemic superspreading was observed in hospitals (nosocomial), funerals (gatherings), and even taxis (transportation). Conversely, aerosol spread of Ebola has also not been completely ruled out either and continues to be debated decades after its discovery.[16]
WHO	In August, 2020 the WHO Infection Prevention and Control Research and Development Expert Group for COVID-19 wrote that the predominant route of transmission of SARS-CoV-2 is consistent with the droplet/contact route. As recently as December 21, 2021 Dr. Mike Ryan, Executive Director, WHO Health Emergencies Programme, emphasized[17] the role of multiple modes of transmission[18] including aerosols, droplets, and surfaces (fomites). In

	environments with extended, close-contacts such as households (or social bubbles), aerosols, droplets, and fomites may all have ample opportunity for transmission but the pandemic cannot be sustained without inter-household spread which maybe have a different mix of transmission routes than in households.[19]
CDC	US-CDC opinion is that fomite transmission of SARS-Cov-2 is unlikely[24] and people are primarily infected through exposure to respiratory fluids carrying the SARS-Cov-2, but these could be droplets or aerosols.[4]
California	On June 17, 2021, California (Cal-OSHA) declared COVID-19 an airborne disease and required employers to provide respirators (e.g. N95) upon request to unvaccinated employees[25] but the US (federal OSHA) only requires face coverings.[26]
Academics	Academics[20][21] have countered the WHO's position stating that SARS-CoV-2 is primarily airborne. In 2021, others have in turn characterized the position that airborne is the primary transmission route as exaggerated[22] and instead it primarily transmits respiratory droplets and, to a lesser extent, via aerosols.[23]

Spread of SARS-Cov-2 aboard flights will be limited by how many infected passengers board

flights, of which 10%-20% are estimated to be potential super spreaders[14][43] based on expert

opinion and observational studies. Unlike many other parts of the world, Hong Kong,[44][45]

Australia and New Zealand conduct testing, tracing, and isolation of arriving passengers from

abroad and publish observational studies of inflight superspreading. An airline Vistara

reported that of 29 flights arriving in Hong Kong potentially up to 1% of their passengers

tested positive.[72] Between December, 2020 and March, 2021 in Australia, wastewater from

24 (64.9%) of the 37 repatriation flights tested positive.[46] Among 6,570 arriving passengers

on these Australia-bound flights, 112 tested positive from which there would be expected 11

super spreaders (112 x 10%). As of October 20, 2020, out of 62,698 arriving passengers, New

Zealand identified 215 who tested positive[27] from which there would be expected 21 super

spreaders (215 x 10%). Indeed, based on testing of arriving passengers, infrequent reporting

or publications aside from exceptional case studies also suggests lower incidence of

superspreading than expected from the number of super spreaders who would be expected to

be aboard these flights.

More broadly, point prevalence of COVID-19 is highly dynamic and has been observed to be

approximately 1% or higher at times in observational community testing of those who could

board an airplane (typically higher for symptomatic or unvaccinated individuals).[47][48] During

periods of high community prevalence, if only 1% of passengers who board airplanes are

positive and at least 10% of them are super spreaders we expect approximately one super

spreader on board every 5 flights for a 200 passenger flight (200 x 1% x 10% = 1/5) well

above the published rate of multiple transmission events aboard these aircraft.

Table 5 lists three alternate hypotheses for why there have been relatively few published

multiple-transmission (superspreading) events on flights is the rapid air filtration aboard

passenger aircraft: mandatory masking, passenger mixing patterns, and rapid HEPA filtration.

Appling Occam's Razor, perhaps the most plausible, explanation of the three is rapid, HEPA

air filtration (often exceeding 15 air exchanges per hour) because it is the greatest

differentiator between passenger airplanes and community settings. In a short time that

Omicron variant has spread around the world, there have already been case studies published

of large super spreading events[74] and cross hallway transmission in quarantine hotels in Hong

Kong[75] suggesting aerosol transmission, yet it is remarkable that considering the densely

packed quarters aboard passenger airplanes there have thus far been no similar case studies

published of mass-transmission of Omicron aboard passenger flights.

Table 5: Possible explanations for lower than expected inflight super spreading.

Mandatory masking	One possible explanation for lower than expected inflight superspreading is that passenger adherence to masking, once it became mandatory, was higher than in the community settings due to enforcement by airlines. Transmission aboard flights (and across rows) was also observed in three flights when masks were worn by most infected passengers[27 36 37] and in one flight when masks were worn by all passengers for the flight duration.[38] Transmission has also been observed and confirmed with genome sequencing in healthcare settings despite both parties being masked maintaining a distance of 3 feet.[39] This is remarkable[40 41] considering thousands of daily flights carried millions of passengers[42] in densely packed seating arrangements with non-uniform implementation and inconsistent or imperfect passenger adherence to control measures such as preflight testing and masking.
Passenger mixing patterns	Another possible explanation for low incidence of multiple transmission (superspreading) aboard flights maybe reduced passenger mixing patterns involving close-contact relative to community settings mixed because passengers are confined to their seats most of the time. Greater transmission is predicted[49] and observed retrospectively[35] for passengers who sit nearby aboard flights. Observational studies aboard ten transcontinental flights showed there are ample opportunities for mixed, close-contact aboard these aircraft (perhaps not as many as in a bar) because passengers not only share bathrooms but frequently walk around inflight (e.g. queuing at bathrooms for

	multiple minutes) especially by aisle-seated passengers on longer flights.[50] They appear to be higher in number and shorter in duration than community.[51][52]
Rapid, HEPA air filtration	The level of ventilation or air filtration is measured by the number of air exchanges per hour (ACH). Passenger aircraft typically use rapid HEPA air filtration as high as 15 air changes per hour (ACH)[53] which itself has been insufficient to completely stop all multiple transmission (superspreading), but still much higher than typical indoor community settings.

The combination of N95 masks with rapid HEPA filtration onboard the aircraft was utilized

for a repatriation flight to South Korea.[61] Public health agencies should also consider

recommending a broader range of masks options based on breathability, fit, cost, and

reusability that provide minimum specifications for protection against aerosols carrying

viruses such as CDC-NIOSH approved N95, N99, or P100 respirators and their equivalents.

Breathability is often raised as a concern with respirators compared to ordinary face

coverings or double masking. N95 respirators have been characterized by the directors of

CDC and NIAID as difficult to breathe,[62][63] but there is a great deal of variation in

breathability among N95 models (disposable and reusable). One laboratory study found N95

more breathable than two masks consisting of a surgical mask beneath a cloth mask.[64]

Effective filtration depends on how well the respirator fits and seals to the face. Another

concern with community use of respirators is fit-failure i.e. whether adequate fit is achieved

without fit-testing. Further studies are needed to validate the fit of respirators worn by

community participants without fit testing. A limited number of trials with small numbers of

participants indicate high filtration using N95 respirators even with suboptimal fit or in the

absence of fit testing and training.[65][66][67][68][69]

Conclusions

Fundamentally, the rate of aerosol (particulate) removal by air filters (HEPA, DIY, etc.) in a room as measured by clean air delivery rate (CADR) must exceed the rate of introduction of these aerosols by a significant margin in order to avoid accumulation of aerosols and achieve rapid clearance (e.g. when introduced by an infected person or smoky source). Outdoor ventilation is generally additive to air filtration (in terms of ACH) except on days when the outdoor air is polluted with wildfire or smoky particulates (e.g. PM 2.5) in which case indoor air filtration is needed to clean the outdoor air too. Experts at Boston School of Public Health[57] and the California Department of Public Health[58] recommend 4 to 6 ACH in community settings to prevent COVID-19. Researchers measuring traces of the SARS-CoV2 coronavirus in the air of a COVID-19 ward of a UK hospital reported they were undetectable once air filtration machines filtered the air in each room every 6 to 12 minutes.[73] To achieve these ACH targets, cost and noise generation concerns with portable air filtration or ventilation upgrades need to be addressed.[59 60]

Unlike healthcare facilities where there are minimum specifications[54] for ventilation and air filtration in many cases exceeding 15 air exchange per hour (ACH), in community settings[55] and schools[56] the CDC (US) recommends increasing air filtration "as high as possible." Specific targets for ACH in community settings are needed.

Indoor ventilation upgrades, portable HEPA purifiers, and respirators (e.g. N95) can remove SARS-Cov-2 particles and its variants, other airborne viruses that cause natural or artificial pandemics (e.g. respiratory RNA viruses[76]), aerosolized bacteria such as anthrax[77], and particulate pollution. However, these can be unaffordable to much of the US and world population.

348
349   As we discovered in the test results, DIY air filtration by combining off-the-shelf components

350   (box fans with heating, ventilation and cooling or HVAC filters) compares favorably in

351   performance (clean air delivery rate, noise) to HEPA air purifiers but at approximately five to

352   ten times lower cost, and can be an affordable option for rapid aerosol removal indoors in

353   homes, clinics, schools, and offices.
