22

23

24 **Abstract**

25

26 **Background**

27 There have been no population-based studies of SARS-CoV-2 testing, PCR-confirmed
28 infections and COVID-19-related hospital admissions across the full paediatric age range.
29 We examine the epidemiology of SARS-CoV-2 in children and young people (CYP) aged
30 <23 years.

31

32 **Methods**

33 We used a birth cohort of all children born in Scotland since 1997, constructed via linkage
34 between vital statistics, hospital records and SARS-CoV-2 surveillance data. We calculated
35 risks of tests and PCR-confirmed infections per 1000 CYP-years between August and
36 December 2020, and COVID-19-related hospital admissions per 100,000 CYP-years
37 between February and December 2020. We used Poisson and Cox proportional hazards
38 regression models to determine risk factors.

39

40 **Results**

41 Among the 1226855 CYP in the cohort, there were 378402 tests, 19005 PCR confirmed
42 infections and 346 admissions, corresponding to rates of 770.8/1000 (95% confidence
43 interval 768.4-773.3), 179.4 (176.9-182.0) and 29.4/100,000 (26.3-32.8) CYP-years
44 respectively. Infants had the highest COVID-19-related admission rates. Chronic conditions,
45 particularly multiple types of conditions, was strongly associated with COVID-19-related
46 admissions across all ages. The hazard ratio for >1 chronic condition type was 12.2 (7.9-
47 18.82) compared to children with no chronic conditions. 89% of admitted children had no
48 chronic conditions recorded.

49

50 **Conclusions**

51 Infants, and CYP with chronic conditions are at highest risk of admission with COVID-19,
52 however the majority of admitted CYP have no chronic conditions. These results provide
53 evidence to support risk/benefit analyses for paediatric COVID-19 vaccination programmes.
54 Studies examining whether maternal vaccine during pregnancy prevents COVID-19
55 admissions in infants are urgently needed.

59

60 **Background**

61 Children are much less likely to experience hospital admission and mortality related to
62 severe acute respiratory syndrome coronavirus-2 (SARS-CoV-2) infection than adults.¹ In
63 Europe in 2020, 1.7% of COVID-19-related hospital admissions were in children <19 years
64 of age.²

65 Whilst early reports during the spring and summer of 2020 indicated less than 5% of SARS-
66 CoV-2 positive cases in the United States,³ China⁴ and Spain⁵ were in children, the
67 epidemiology has changed over time and place, particularly in association with vaccination
68 policy and access, with children under 10 years of age being the dominant population
69 infected in the latter part of 2021 in the UK..⁶

70 Over the course of the pandemic our understanding of how SARS-CoV-2 infection affects
71 children has also improved. Children who experience more severe symptoms of SARS-CoV-
72 2 may present with acute infection symptoms such as fever, cough, shortness of breath,
73 nausea/vomiting, or upper respiratory symptoms.⁷⁻⁹ Children may also present with an acute
74 inflammatory syndrome, paediatric inflammatory syndrome temporally associated with
75 SARS-CoV-2 (PIMS-TS; also referred to as multisystem inflammatory syndrome related to
76 COVID - MIS-C), several weeks after initial infection.¹⁰⁻¹² Children aged <2 years old appear
77 to be over-represented among children admitted to hospital with acute symptoms of SARS-
78 CoV-2 infection, whereas children aged 10 years or older account for the largest proportion
79 of admitted PIMS-TS cases.^{8 13}

80 Two preprints indicate that among children admitted to hospital with SARS-CoV-2 or PIMS-
81 TS, those with specific chronic respiratory, neurological, gastrointestinal or cardiovascular
82 conditions, and particularly children with multiple comorbidities, were at increased risk of
83 Paediatric Intensive Care Unit (PICU) admission or death. Infants and teenagers appeared
84 to have higher odds of these severe outcomes compared to children aged 1-4 years old.^{14 15}
85 A lower reported risk of severe disease and, until 2021, relatively lower rates of infection in
86 children have supported a narrative that the benefits and risks (primarily of myocarditis
87 following second dose mRNA vaccines in young men^{16 17}) of vaccinations in children are
88 finely balanced.

89 Most studies of paediatric SARS-CoV-2 infection have been case series of infected or
90 hospitalised children, making calculations of population-based risks of confirmed infections
91 and associated admissions among different groups of children, including children with
92 chronic conditions, impossible. A recent study presented population-based risks of COVID-

93 19-related admission for children with asthma, indicating an increased risk that supports
94 vaccine strategies targeted to this group.¹⁸ Our aim was to provide population based
95 estimates of risk of SARS-CoV-2 testing, PCR confirmed infections and COVID-19 related
96 admissions in children and young people (CYP) based on age, presence of multiple chronic
97 conditions, and socioeconomic status, that could support vaccination and other policy
98 recommendations across the whole paediatric population.

99 **Methods**

100 *Data sources*

101 We used a national birth cohort of all children and young people (CYP) born in Scotland from
102 1997 onwards, developed from administrative health datasets linked to public health
103 surveillance data on SARS-CoV-2 test results, originally constructed for the PICNIC study.¹⁹
104 CYP born in 1997 onwards were included. Birth registrations comprised the cohort spine,
105 and CYP are linked over time and between databases using the Community Health Index
106 (CHI) number, a unique personal identifier recorded at all interactions with the Scottish
107 National Health Service (NHS). Table 1 summarises the databases and variables used in
108 this study.

109

110 **Table 1. Datasets and variables from the national Scottish birth cohort used in the**
 111 **study**

Dataset	Dataset details	Variables used
National Records for Scotland (NRS) birth registrations	Vital registration data on all children born in Scotland and their parents, collected via registry offices	Week and year of birth; Baby Sex; Socio-economic position (parents' occupation at birth).
Scottish Morbidity Record (SMR)-01	Contains data on post-neonatal admissions and day cases to all NHS hospitals in Scotland	Admission and discharges dates; Primary and secondary diagnoses during admission; Type of hospital admission; Admission and discharge data from Intensive Care Unit (ICU).
SMR-02 (maternity records)	Contains data on all maternity admissions (including deliveries) in Scotland	Estimated gestational age; birth weight; number of older siblings (parity).
COVID-19 Tests	Contains data on all PCR- and antigen tests for SARS-Cov-2 with results and dates	Date of testing; Type of test; Result.
National Records for Scotland (NRS) death registrations	Vital registration data on children who died in Scotland	Date of death; Cause of death.
Scottish Birth Records (SBR)	Contains data on all children born in NHS hospitals, with data on neonatal admissions in and after April 2003	Diagnoses recorded at or shortly after birth ; Primary and secondary diagnoses at birth admission.
CHI register	Contains data on migration in/out Scotland	Migration outside Scotland.
Child Health Surveillance Programme-School	Contains data school health visits	Height and weight at age 5

112

113

114 *Study population and follow-up*

115 We included CYP born in Scotland from 1st April 1997 to 31st December 2020. Children born
116 at less than 24 completed weeks' gestation or with a birthweight <500 grammes were
117 excluded to ensure stillbirths were not inadvertently included.²⁰ CYP whose mothers were
118 not resident in Scotland at the time of delivery, and CYP who migrated out of Scotland
119 before 1st February 2020 were also excluded. For analyses of SARS-CoV-2 tests and
120 positive test results (from now on referred to PCR-confirmed infections), CYP were followed
121 from birth or the 1st August 2020 (whichever occurred last), until death, migration from
122 Scotland, or their 23rd birthday, whichever occurred first. 1st August 2020 was chosen as the
123 follow-up start date for analyses of tests and PCR-confirmed infections since this is when
124 testing for SARS-CoV-2 became commonly available in the community (rather than solely in
125 hospitals) for children of all ages.²¹ For calculation and analyses of rates of COVID-19-
126 related admissions, we used the follow-up start date as the 1st February 2020. This allowed
127 us to include all COVID-19-related hospital admissions since PCR testing for SARS-CoV-2
128 was available for suspected cases in hospital from January 2020.

129 *Outcomes*

130 Our primary outcomes were rates of a) SARS-CoV-2 PCR tests (positive or negative); b)
131 PCR-confirmed SARS-CoV-2 infections; c) COVID19-related hospital admissions. We also
132 considered as secondary outcomes d) PIMS-TS admissions and e) COVID19-related
133 intensive care unit (ICU) stays.

134 For a), we included all SARS-CoV-2 PCR tests recorded between 1st August 2020 and 31st
135 December 2020 in the COVID19 Tests Dataset. The samples were collected in hospitals,
136 primary care, via national testing centres, or self-collection via home test kits. We did not
137 include antigen (lateral flow device) test results, as they were not comprehensively
138 represented in the COVID19 Tests dataset during 2020 (only 5% of test results in the cohort
139 during the study period were from lateral flow devices). We defined as duplicate tests
140 multiple tests taken on the same day, in the same CYP, with the same result, irrespective of
141 whether they were taken at different locations. All duplicate tests, whether positive or
142 negative, were excluded when calculating testing rates. For b), a PCR-confirmed SARS-
143 CoV-2 infection was defined as the first record of a positive SARS-CoV-2 PCR test result
144 (the index positive test) recorded in the COVID19 Tests dataset between 1st August 2020 and
145 31st December 2020. Public Health Scotland recommends excluding all repeat positive tests
146 within 90 days of the index positive sample date, and less than 5 CYP had multiple positive
147 results beyond this time period. Therefore, only the first positive SARS-CoV-2 PCR test

148 result for each child was included when calculating rates of PCR-confirmed SARS-CoV-2
149 infections, and identifying COVID-19-related hospital admissions.

150 We included all COVID-19-related hospital admissions (outcome c) between 1st February
151 and 31st December 2020. To define COVID-19 related hospital admissions, we first linked
152 episodes in the hospital admission dataset (Scottish Morbidity Record-01; Table 1) into
153 admissions by assuming that episodes where the difference between the admission date
154 and previous discharge date was ≤ 1 day²² indicated the same admission. Second, we
155 identified COVID-19 related admissions where: (i) an individual had tested positive for
156 SARS-CoV-2 up to 14 days prior to hospital admission, on the day of admission, or in
157 between the hospital admission and discharge date, and/or (ii) an International Classification
158 of Diseases-version 10 (ICD-10) diagnostic code for COVID-19 (U07.1 – U07.2) had been
159 recorded during an admission as a primary or secondary diagnosis.

160 Since the ICD-10 code for PIMS-TS (U07.5) was introduced at the end of the follow-up
161 period, we used other ICD-10 codes indicating systemic inflammatory response syndrome of
162 infectious origin without organ failure (R65X), cardiogenic shock (R57X) or other specified
163 systemic involvement of connective tissue (M35.8), suggestive of PIMS-TS recorded during
164 an admission which had a positive SARS-CoV-2 PCR test within 28 day prior to the
165 admission date.

166 A COVID-19-related intensive care unit (ICU) stay (outcome e) was defined where a child
167 had an SMR-01 episode with 'significant facility' recorded with a positive SARS-CoV-2 PCR
168 test to 21 days prior to the start of, or during, the ICU stay. ICU episodes where the
169 difference between the ICU admission date and previous ICU discharge date was ≤ 1 day
170 were assumed to indicate the same ICU stay.

171 *Risk factors*

172 We examined four risk key factors for outcomes a-c): age group, sex, family socio-economic
173 position (SEP) and history of chronic conditions. Age group was defined on 1st February
174 2020 as the following five categories: <1 year (this also includes children born during 2020),
175 1-4 years, 5-11 years, 12-17 years and 18-22 years. We chose these age groups to reflect
176 likely mixing patterns based on age (i.e. prior to formal childcare, nursery/preschool, primary
177 school, secondary school, and higher/further education or work). Sex was recorded on the
178 birth record. Family SEP was defined using parents' (father's, or mother's if the birth was not
179 jointly registered) occupation recorded on birth registration. This was coded using the UK
180 National Statistics Socio-economic Classification (NS-SEC).²³ We collapsed the NS-SEC

181 classes into three groups: high SEP (managerial and professional occupations), middle SEP
182 (intermediate occupations) and low SEP (routine and manual occupations). We identified
183 history of chronic conditions by examining ICD-10 diagnostic codes recorded in SMR-01 in
184 the previous five years. For children aged less than five years old at the start February 2020
185 or born during 2020, we used all available SMR-01 data and any diagnoses recorded on
186 Scottish Birth Records. The code list for identifying chronic conditions was developed by
187 Hardelid et al;²⁴ and classifies chronic conditions into 8 types depending on body system:
188 developmental/mental health, blood/cancer, chronic infections, respiratory,
189 metabolic/gastrointestinal/endocrine/genitourinary, musculoskeletal/skin
190 neurological/sensory, and cardiac conditions. We grouped the history of chronic conditions
191 as none, one type of condition, and more than type of chronic condition.

192 We further explored whether gestational age and the number of older siblings affected
193 outcomes b) and c) in children aged <5 years, and BMI in CYP aged 5-17, after adjusting for
194 the four key risk factors. Gestational age was coded into a binary variable: preterm (<37
195 weeks) and term/late term (≥ 37 weeks). Number of older siblings (indicated by parity
196 recorded on maternity records) was grouped into a three-category variable: no older siblings,
197 one older sibling and two or more older siblings. BMI was derived from the Child Health
198 Surveillance Programme -School dataset, which includes height and weight measurements
199 for children starting their first (reception) year at primary school (at age 5 years), categorised
200 using the British 1990 growth reference standards²⁵ as underweight (<5th percentile), healthy
201 weight (5th to <85th percentile) and overweight/obese ($\geq 85^{\text{th}}$ percentile).

202 *Statistical analyses*

203 We calculated rates of outcomes a) and b) per 1,000 CYP years and outcome c) per
204 100,000 CYP-years with 95% confidence intervals, according to each of the risk factors. We
205 estimated the median length of stay with interquartile ranges (IQRs) for COVID-19 related
206 hospital admissions.

207 We examined the association between risk factors and testing rates using Poisson
208 regression models with robust standard errors to account for multiple tests per child. To
209 examine the association between risk factors and PCR-confirmed SARS-CoV-2 infection,
210 and COVID19-related admission risk we used Cox proportional hazards regression models.
211 Where a child had multiple COVID-19-related admissions, only the first was included in the
212 Cox proportional hazards models. For each primary outcome, we first fitted an overall model
213 including all ages. We included age group, sex, SEP and history of chronic conditions a
214 priori as risk factors in the main model. We tested for interaction with age group and each of

215 the other main risk factors using the Wald test. Two-sided p -values <0.05 were considered
216 statistically significant.

217 Based on these results, we then fitted models for each primary outcome stratified by age
218 group if a statistically significant interaction with age was identified for any of the other
219 variables or if we identified non-proportional hazards. In further analyses for ages <5 years
220 old we included parity and gestational age as additional risk factors in the models; and for
221 ages 5-17 years we included BMI category. We tested the proportional hazards assumption
222 of the Cox model by inspecting plots of Schoenfeld residuals²⁶ and survival curves according
223 to each main risk factors.

224 As there was only a small number of events for our secondary outcomes, we did not carry
225 out detailed statistical analyses. We report the number of cases, median length of stay and
226 age (with IQRs) for these outcomes.

227 All analyses were based on complete cases, as only a small number of CYP and missing
228 values for any of the main variables. All statistical analyses were performed using Stata
229 16.0.

230 *Sensitivity analyses*

231 We repeated the analyses for outcome c) using a more specific definition of a COVID-19-
232 related admission restricted to emergency admissions with U07.1 or U07.2²⁷ as the primary
233 diagnosis.

234 **Results**

235 This study included 1,226,855 CYP (Figure 1). Baseline characteristics of the participants
236 are presented in Table 2. The median age on February 2020 was 11 years (IQR 5-17), and
237 5.4% of the cohort (66,974/1,226,855 CYP) had at least one chronic condition recorded in
238 their hospital or birth record in the previous five years.

* As on 1st February 2020; aged<1yr includes those born between 1 February 2020 and 31 December 2020. ** From UK National Statistics Socio-economic Classification (NS-SEC): SEP (managerial and professional occupations), middle SEP (intermediate occupations), low SEP (routine and manual occupations). ***Includes any chronic conditions recorded in the hospital records in the previous five years. ***As recorded in the Child Health Surveillance Programme-School at aged 5 and standardised according to the British 1990 growth reference standards (Cole 1998): underweight (<5th percentile), normal weight (5th to <85th percentile), overweight/obese (≥85th percentile).

245

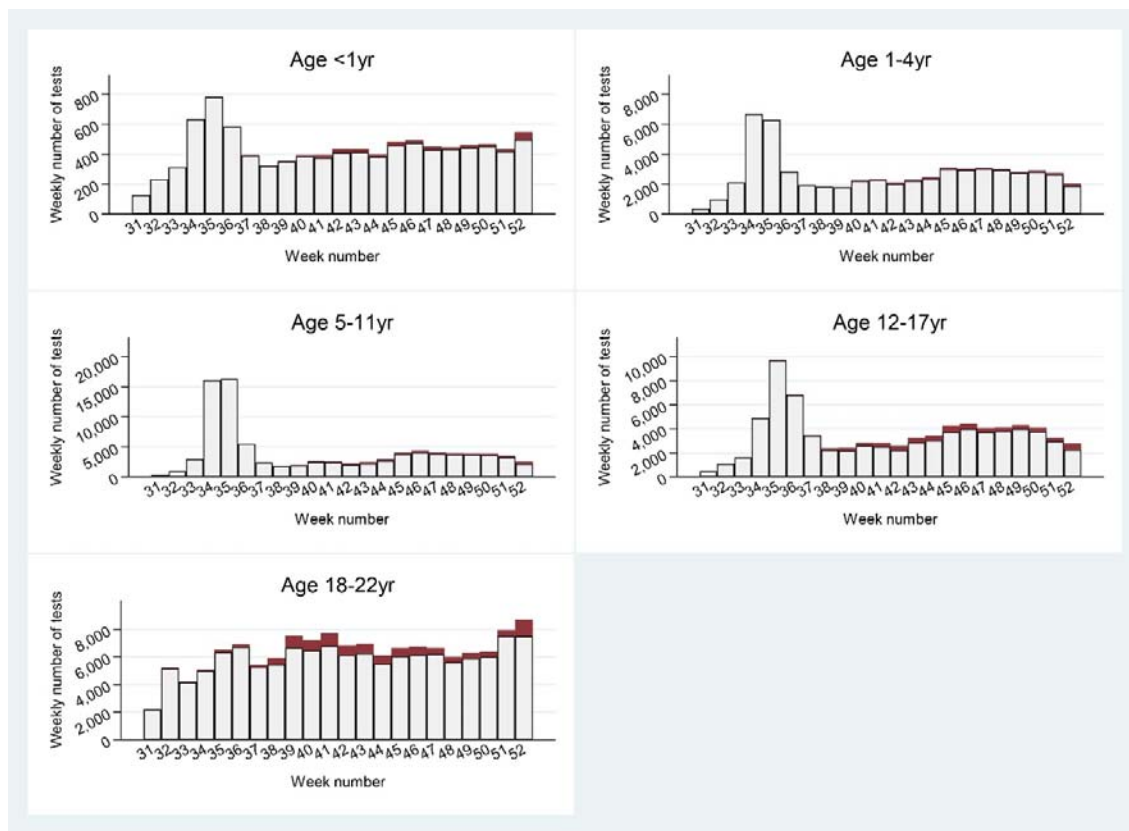

246 *SARS-CoV-2 testing*

247 Between 1st August (week 31) to 31st December 2020 (week 52) we identified 378,402 PCR
248 tests linked to 256,741 CYP; hence 20.9% of CYP in the cohort had at least one test. Figure
249 2 shows the weekly number of PCR tests by age group. The majority of CYP had been
250 tested only once (200,288; 78.0%); 40,188 (15.7%) had been tested twice and 16,265
251 (6.3%) more than twice.

252 The crude testing rate was 770.8 (95%CI 768.4-773.3) per 1,000 CYP-years. Testing rates
253 varied by age group and chronic conditions: children aged 1-4 years, young adults (age 18-
254 22 years), and those with more than one chronic condition recorded had the highest testing
255 rates (Appendix Table 1 & 2). Children aged <5 years born preterm were also more likely to
256 be tested compared to children born at term (Appendix Table 3).

257 Models that mutually adjusted for all four main predictors suggested increasing age (and
258 particularly an age of 18-22 years) and a history of chronic conditions were strongly
259 associated with being tested (Table 3). As there was a statistically significant interaction term
260 between age group and each of the other risk factors, we conducted age group-stratified
261 analyses (Table 4). A history of chronic conditions was strongly associated with higher
262 testing rates, with the size of the effect being the largest among infants

263

282

283

284 *PCR-confirmed infections*

285 Among the 378,402 PCR tests identified in the cohort, 20,003 (5.3%) were positive and
286 7,275 (1.9%) were void. Excluding multiple positive tests per CYP, this corresponds to
287 19,005 PCR confirmed index infections in 7.4% (19,005/ 256,741) of the CYP who were
288 tested between 1st August 2020 and 31st December 2020.

289 The overall rate of PCR-confirmed infections was 179.4 (95% CI 176.9-182.0) per 1,000
290 CYP-years. Young adults (aged 18-22 years) had the highest rates of PCR-confirmed
291 infections and those aged 1-4 years the lowest (Appendix Table 4 & 5). Infants had the
292 highest PCR-confirmed infection rates in preschool children, otherwise infection rates were
293 positively correlated with age. Among the infants who tested positive 20.3% (56/276) were
294 aged <3months and 38.8% (107/276) aged <6months. Overall, CYP from higher SEP groups
295 and those with no history of chronic conditions had a higher risk of PCR-confirmed infection
296 (Table 3). As we identified statistically significant interaction terms between age group and
297 each of the other main risk factors, we conducted stratified analyses by age group (Table 5).
298 These results showed that among infants and preschool children, PCR-confirmed infection
299 rates were lower among higher SEP groups, whereas among CYP aged 12 and above,
300 children from higher SEP groups were more likely to be infected. Infants with chronic
301 conditions had higher infection rates than those without; the opposite was true for CYP aged
302 ≥ 12 years.

303 Additional analyses suggested that children aged <5 years with one older sibling had a
304 reduced risk of a PCR confirmed infection compared to children with no older siblings (HR
305 0.63 (95%CI: 0.49-0.81) and 0.86 (95%CI: 0.76-0.98) for infants and 1-4 year olds,
306 respectively, Appendix Table 6). Further, in children aged 12-17 years, being
307 overweight/obese increased the risk of a PCR-confirmed infection compared to being of
308 normal BMI (HR: 1.07 (95%CI: 1.00-1.15), Appendix Table 6).

313

314 *COVID19-related-hospital admissions*

315 Between 1st February 2020 and 31 December 2020, 55,940 CYP in the cohort were admitted
316 to hospital at least once, accounting for 81,312 admissions. Of these admissions, 346 (0.6%)
317 in 318 CYP were identified as COVID-19-related admissions. 25 CYP were admitted more
318 than once. The median time to re-admission was 5 (IQR 2-12) days. The median length of
319 stay was 2 days (IQR 1-4 days). There were 110 admissions between February and July
320 (31.8%) and 236 (68.2%) between August and December (Figure 3).

321 Of the 346 COVID-19-related admissions 203 (58.7%) had a U07.1/U07.2 recorded as
322 primary diagnosis and 258 (74.6%) were temporally associated with a SARS-CoV-2 positive
323 test with or without a primary or secondary U07.1/U07.2 diagnosis (Figure 4).

324 The overall COVID-19 related admission rate was 29.4/100,000 (95%CI 26.3-32.8) CYP
325 years. Infants had the highest COVID-19 related admission rate across the age groups:
326 120.6/100,000 (95%CI 92.2-157.9). CYP with more than one chronic condition type recorded
327 had the highest admission rates across all age groups (Appendix table 7 & 8). Overall,
328 12.0% ($n=38$) of the 318 CYP admitted had at least one type of chronic condition, and 6.9%
329 ($n=22$) had multiple types of chronic conditions recorded; thus 88% of admitted CYP did not
330 have an underlying chronic condition.

331 Of the CYP with chronic conditions who had a COVID-19 related admission,
332 neurological/sensory conditions were the common condition type recorded among children
333 aged<12 years, whereas among those aged 12-22 years the most common conditions were
334 developmental/mental health conditions followed by
335 metabolic/gastrointestinal/endocrine/genitourinary conditions.

336 Across all ages, presence of one or more chronic condition increased the risk of COVID-19-
337 related admissions and CYP from lower SEP groups had the highest risk of COVID-19-
338 related admission (Table 3). We identified statistically significant interaction terms between
339 age group and each of the other main risk factors, and therefore conducted age-stratified
340 analyses (Table 6). Having more than one chronic condition remained the strongest risk
341 factor for COVID-19-related admission across all age groups. There was no statistically
342 significant association between prematurity, number of older siblings, or BMI category and
343 COVID-19 related hospital admission risk (Appendix Table 9).

344

356

357

358 *ICU admissions and PIMS-TS cases*

359 Thirteen (3.8%) of the 346 COVID-related admissions involved an ICU attendance,
360 accounting for 1.2% of the 1,238 ICU admissions in CYP during the study period. Around
361 half of these admissions were in CYP with a history of one or more types of chronic
362 conditions. The median age of CYP admitted to ICU was 14 years (IQR 9-19 years) and the
363 median length of stay at ICU was 6 days (IQR 2-7 days). Half of COVID-related ICU
364 admissions were in boys.

365 We identified less than five admissions with a diagnosis suggestive of PIMS-TS and
366 temporally associated with a positive PCR test (<28 days prior admission by definition), all in
367 males with an age spanning from 9 to 14 years. The median length of stay at admission was
368 10 days (IQR 6-14).

369 *Sensitivity analyses*

370 Among the 346 COVID related admissions, 199 (57.5%) were emergency admissions with a
371 primary diagnosis of U07.1/U07.2. Using the more specific definition, the COVID-19 related
372 hospital admission rates were 107.0 (95% CI 80.4-142.4), 13.4 (9.0-19.8), 8.0 (5.6 – 11.7),
373 9.3 (6.3-13.6) and 27.7 (21.6-35.5) per 100,000 CYP years in age groups <1, 1-4, 5-11, 12-
374 17 and 18-22 years respectively (Appendix Table 10 &11). This is 1.8 to 2 times higher than
375 the more inclusive definition for CYP aged ≥ 1 year. Refitting the Cox proportional hazard
376 models by age using the specific definition confirmed that presence of one or more chronic
377 conditions remained the only significant risk factor for hospital admission (Appendix Tables
378 12 & 13). The median length of stay remained 2 days (IQR 1-5).

379 **Discussion**

380 Over one fifth of CYP in Scotland had at least one SARS-CoV-2 PCR test during 2020, and
381 1.5% had a PCR-confirmed infection. Testing rates increased with increasing age. PCR-
382 confirmed infection rates were highest in 18–22-year-olds, followed by secondary school
383 children and infants. CYP with chronic conditions were more likely to be tested, but CYP with
384 chronic conditions of secondary school age or older were less likely to have a PCR
385 confirmed infection. Whilst COVID-19 related hospital admissions were uncommon (less
386 than 3 per 10,000 CYP admitted in 2020), infants and those with multiple types of chronic
387 conditions recorded had the highest COVID-19 related-admission rates. Preschool children
388 from lower SEP groups were more likely to have PCR-confirmed infection, and secondary
389 school children and young adults from lower SEP groups less likely. Across all ages, SEP
390 was significantly associated with COVID-related hospital admission. We identified no

391 statistically significant associations between prematurity, nor BMI and COVID-related
392 admission risk; however the number of children admitted was small.

393 The well-established Scottish data linkage infrastructure allowed us to include data for all
394 CYP born in Scotland since 1997, thereby minimising selection bias and loss to follow-up.
395 We relied on linkage between hospital admission and public health surveillance data to
396 define COVID-19-related admissions, allowing us to examine the robustness of our
397 definitions in the linked data, rather than only relying on time difference between SARS-CoV-
398 2 positive test and hospital admission alone. Importantly, by using a national birth cohort for
399 this study, we could examine variations in population-based rates of SARS-CoV-2 testing,
400 PCR confirmed infections and COVID-19-related hospital admissions across the full CYP
401 age range, rather than only examining risk factors for ICU admission and death in
402 hospitalised children. Using a population-wide study sample also minimises the risk of
403 collider bias²⁸ which may risk validity in studies only including hospitalised patients.

404 Despite the use of a national birth cohort, we were unable to determine risk factors for rarer
405 outcomes including COVID-19-related ICU admission and cases of PIMS-TS. Pooling results
406 across multiple countries with data linkage capabilities allowing national CYP birth cohorts to
407 be created, could provide reliable risk estimates for these more severe outcomes following
408 SARS-CoV-2 infection in CYP.

409 Further, this study included data from the first year of the pandemic, when wildtype (until
410 November 2020), followed by Alpha (dominant from December 2020) SARS-CoV-2 variants
411 were circulating in Scotland. This study will need to be repeated to examine the impact of
412 new circulating variants, including Delta and Omicron, and changing transmission dynamics
413 as vaccination of adults appear to be concentrating virus circulation among younger age
414 groups.²⁹ Recommendations to vaccinate high risk children aged 12 years and older against
415 SARS-CoV-2 with two doses of Pfizer-BioNTech (BNT162b2; COMIRNATY) COVID vaccine
416 was introduced in July 2021 in the UK; prior to this only children aged 12 and older with
417 severe neurodisability, and 16-17 year olds with underlying conditions were recommended
418 vaccination.³⁰ In August and September 2021, these recommendations changed to advise
419 vaccination with one dose for all 16-17 olds (due to risk of myocarditis), and then all children
420 aged 12 years and above respectively.^{31 32} The US Food and Drug Administration approved
421 the Pfizer-BioNTech vaccine for use in 5-11 year olds in late October 2021. Vaccination of
422 children is likely to change risks of hospital admission, particularly among children with
423 multiple chronic conditions. Whilst the benefits of vaccines may extend to non-health
424 domains (e.g. school absences), further studies will need to examine whether the COVID-19
425 vaccination programme has amended the admission risks reported in this study. However,

426 the results reported here provide a baseline during the first pandemic year against which
427 more recent data can be compared.

428 We based our classification of chronic conditions on coded information in SMR-01 and SBR
429 records; this may mean we have missed some conditions that are primarily managed in
430 primary or community care settings. Our classification of socio-economic position was based
431 on parental occupation derived from birth certificates, however, particularly among older
432 CYP this may not reflect current socio-economic circumstances.

433 We highlight that infants have the highest admission risk among CYP, despite higher testing
434 rates in older children and young adults. A previous systematic review (preprint) has
435 indicated that infants are also at highest risk of requiring PICU admission once in hospital
436 with COVID-19 disease.¹⁴ However, admission rates in infancy related to SARS-CoV-2
437 (1/1000 child-years) is lower than admission rates associated with confirmed influenza
438 (2/1000 child-years)³³ or respiratory syncytial virus infections (22/1000-child years).³⁴ Future
439 research should examine how COVID-19 vaccination programmes for pregnant women and
440 older children, and removal of non-pharmaceutical interventions to control population mixing,
441 affect infant SARS-CoV-2 admission rates.

442 We demonstrated that a history of chronic conditions, and particularly living with multiple
443 different types of chronic conditions, was the most prominent risk factor for COVID-19
444 related hospital admission rates among CYP, however the vast majority of admitted children
445 had no chronic conditions recorded. Children with chronic conditions also experience higher
446 hospital admission rates for other conditions and injuries.³⁵ CYP with chronic conditions were
447 more likely to be tested than those without, however in older age groups CYP with chronic
448 conditions were less likely to be positive. This may reflect lower threshold for testing among
449 high-risk groups.

450 Preschool children from lower SEP groups (indicated by parental occupation recorded on the
451 birth certificate) had higher risks of PCR-confirmed infection than children from higher SEP
452 groups. This may be because younger children are spending more time in the home with
453 their parents, and their risk of infection is therefore more strongly associated with their
454 parents' occupation (and ability to work from home). In older CYP, we instead identified
455 higher PCR-confirmed infection rates among higher SEP groups, despite lower testing rates.
456 This may be due to CYP from lower SEP groups being less likely to attend post-16
457 education, including university. Large outbreaks occurred in universities in Scotland in the
458 autumn of 2020, which led to a surge in case numbers in 18-22 year olds.³⁶ Linkage
459 between SARS-CoV-2 test results, hospital admission and education data are required to

460 confirm whether exposure in education settings can explain these differences in infection
461 risk.

462 Low SEP at birth was also a risk factor for COVID-19-related admission in CYP in the overall
463 model (incorporating all ages). This confirms previous reports which have indicated higher
464 risk of severe outcomes in hospitalised adult COVID patients from more deprived areas,³⁷
465 and higher all-age hospital admission rates in areas with higher area deprivation scores.^{38 39}
466 Although we did not identify SEP as a significant risk factor for admission in age group
467 specific models, COVID-19 related admission rates in children are much lower than in
468 adults. Therefore, systematic differences in admission rates by SEP among specific age
469 groups of CYP are harder to detect, even when using national data.

470 Our results showing that COVID-19 related admission rates in CYP peak in infancy indicates
471 that further research and efforts to prevent COVID-19 admissions in children should include
472 a focus on this age group. Pregnant women in Scotland are recommended to receive two
473 doses of Pfizer/BioNTech COVID-19 vaccine.⁴⁰ As for pertussis^{41 42} and influenza,^{43 44}
474 maternal vaccination during pregnancy could protect young babies from SARS-CoV-2
475 infection, however no studies to date have examined this. Further, given that CYP with
476 chronic conditions are more likely to be admitted to hospital admission with COVID-19
477 disease than other CYP, studies monitoring the effectiveness of COVID-19 vaccines against
478 severe outcomes in these high-risk groups are required to determine whether vaccination
479 reduces the risk of admission.

480 We identified a peak in COVID-19-related hospital admissions in infants, and presence of
481 chronic conditions as the strongest risk factor for hospital admissions in CYP, although the
482 majority of admitted children did not have chronic conditions recorded. Further studies are
483 urgently needed to examine whether maternal vaccine during pregnancy prevents COVID-19
484 admissions in infants. These data also provide baseline risks of infection and hospital
485 admission for risk-benefit assessments of childhood vaccination, particularly for preschool
486 children.
