Abstract

Vaccination-based exposure to spike protein derived from early SARS-CoV-2 sequences is the key public health strategy against COVID-19. Successive waves of SARS-CoV-2 infections have been characterised by the evolution of highly mutated variants that are more transmissible and that partially evade the adaptive immune response. Omicron is the fifth of these “Variants of Concern” (VOC) and is characterised by a step change in transmission capability, suggesting significant antigenic and biological change. It is characterised by 45 amino acid substitutions, including 30 changes in the spike protein relative to one of the earliest sequences, Wuhan-Hu-1, of which 15 occur in the receptor-binding domain, an area strongly associated with humoral immune evasion. In this study, we demonstrate both markedly decreased neutralisation in serology assays and real-world vaccine effectiveness in recipients of two doses of vaccine, with efficacy partially recovered by a third mRNA booster dose. We also show that immunity from natural infection (without vaccination) is more protective than two doses of vaccine but inferior to three doses. Finally, we demonstrate fundamental changes in the Omicron entry process in vitro, towards TMPRSS2-independent fusion, representing a major shift in the replication properties of SARS-CoV-2. Overall, these findings underlie rapid global transmission and may alter the clinical severity of disease associated with the Omicron variant.
Introduction

Protection against Severe acute respiratory syndrome coronavirus-2 (SARS-CoV-2) associated disease (COVID-19) is currently reliant on a range of vaccine technologies that induce immunity to the spike protein of the virus that first emerged in Wuhan city, China in 2019. Such early variant vaccines have become the cornerstone of the global public health response to SARS-CoV-2 but are threatened by the successive emergence of Variants of Concern (VOC) displaying increased transmissibility and/or evasion of adaptive immunity. The evolution of SARS-CoV-2 variants with high transmission rates, increase the risk of the generation of variants of the virus with novel properties that may compromise this crucial element of the public health response. The balance between transmission advantage and immune evasion has resulted in the evolution of five VOCs that display these characteristics to varying degrees. The Beta (B.1.351 in Pango nomenclature) and, to a lesser extent, Gamma (P.1) variants were associated with immune evasion in vitro and spread locally but never dominated globally. In contrast, the Alpha (B.1.1.7) and Delta (B.1.617.2) VOCs attained a worldwide distribution and were responsible for significant waves of infections associated with an increase in reproduction number (R₀). Both variants harbour mutations at position 681 within the polybasic furin cleavage site (a histidine in Alpha and an arginine in Delta); changes associated with enhanced cell entry that likely confer an intrinsic transmission advantage. Alpha displayed lower immune evasion properties compared to Beta but higher transmission. Alpha was in turn replaced by the Delta variant that displayed more significant immune evasion in addition to enhanced furin cleavage.

Omicron is the fifth variant to be named as a VOC by the World Health Organisation (WHO) and the third (after Alpha and Delta) to achieve global dominance. The Omicron lineage (B.1.1.529) was first detected in mid-November 2021 in Botswana, South Africa and quarantined travellers in Hong Kong. It has split into three divergent sublineages (BA.1, BA.2 and BA.3) of which BA.1 has spread rapidly around the world. The BA.1 Omicron genome encodes 30 amino acid substitutions relative to Wuhan-Hu-1 within the spike glycoprotein (Fig.1), 15 of which are in the receptor-binding domain (RBD) and 9 within the receptor-binding motif (RBM), the RBD subdomain that interacts with the human ACE2 receptor. Six of these mutations (G339D, N440K, S477N, T478K, Q498R and N501Y) enhance binding affinity to the human ACE2 receptor. Combinations such as Q498R and N501Y may enhance ACE2 binding additively. Overall, the Omicron RBD binds to the human ACE2 with approximately double the affinity (x2.4) of the Wuhan RBD. Seven Omicron RBD mutations (K417N, G446S, E484A, Q493R, G496S, Q498R and N501Y) are associated with decreased antibody binding, importantly falling in epitopes corresponding to the three principal classes of RBD-specific neutralising antibodies.
Three deletions (amino acids 69-70, 143-145 and 211) and an insertion (at site 214) are also present in the amino-terminal domain (NTD) of the Omicron spike glycoprotein. The 69-70 deletion is also found in the Alpha and Eta (B.1.525) variants and is associated with enhanced fusogenicity and incorporation of cleaved spike into virions\textsuperscript{10}. This deletion can also be used as a useful proxy for prevalence estimates in the population by S-gene target failure (SGTF) using the TaqPath\textsuperscript{TM} (Applied Biosystems, Pleasanton, CA) diagnostic assay. Deletions in the vicinity of amino acids 143-145 have been shown to affect a range of NTD-specific neutralising antibodies\textsuperscript{11,12}. Two mutations (N679K and P681H) at the S1/S2 furin cleavage site (FCS), have individually been found to enhance furin cleavage in other variants, contributing to enhanced infectivity, while a third (H655Y, also present in the Gamma VOC) occurs in the vicinity of the FCS\textsuperscript{13}. The role of these changes in combination requires further investigation. Several mutations, such as the deletion at site 211, are not present at high frequency in other VOCs in the global sequencing data, suggesting historic negative selection\textsuperscript{14}. Outside the spike protein, 15 amino acid substitutions are present and require further characterisation. For example, a deletion within NSP6 (105-107) may contribute to immune evasion through virus-induced cellular autophagy\textsuperscript{15}.

Critically, emerging data indicate that the Omicron variant evades neutralisation by sera obtained from people vaccinated with 1 or 2 doses of vaccine, especially when antibody titres are waning. Indicative studies have shown that 3 doses of Wuhan-strain based vaccines may provide only partial protection from infection with this variant, including unpublished data made available as a press release from Pfizer. Immune evasion by Omicron may have contributed to the extremely high transmission rates in countries with high vaccination rates or natural immunity (R\textsubscript{0} of 3-5 in the UK)\textsuperscript{8,16-25}.

In this study, we aimed to investigate the antigenic and biological properties of the Omicron variant that might underly immune evasion and increased transmission of the virus. We demonstrate that vaccine effectiveness is significantly reduced against the Omicron variant in association with neutralising antibody responses from dual and triple recipients of the BNT162b2 (Pfizer), ChAdOx1 (Astra Zeneca) and mRNA-1273 (Moderna) COVID-19 vaccines. Further, using live virus culture and viral pseudotypes, we describe an altered entry pathway that favours endosomal fusion over the TMPRSS2-dependent, cell surface fusion utilised by all previous variants of SARS-CoV-2. In summary, Omicron exhibits significant antigenic and biological changes that underpin immune evasion and hyper-transmissibility and could affect the pathogenesis and clinical severity of disease.
Results

The Omicron variant of SARS-CoV-2 displays substantial change within spike predicted to affect antigenicity and furin cleavage

The Omicron variant is characterised by significant changes within the RBD of the spike glycoprotein, regions targeted by class 1, 2, and 3 RBD-directed antibodies, and within the NTD supersite (Fig. 1A). Deep mutational scanning (DMS) estimates at mutated sites are predictive of substantially reduced monoclonal and polyclonal antibody binding and altered binding to human ACE2 (Fig. 1B)26. Fourteen mutations (K417N, G446S, E484A, Q493R, G496S, Q498R and to a lesser extent, G339D, S371L, S373P, N440K, S477N, T478K, N501Y and Y505H) may be predicted to evade antibody binding based on a calculated escape fraction (a quantitative measure of the extent to which a mutation reduces polyclonal antibody binding by DMS). Seven Omicron RBD mutations (K417N, G446S, E484A, Q493R, G496S, Q498R and N501Y) have been shown previously to be associated with decreased antibody binding, importantly falling in epitopes corresponding to three major classes of RBD-specific neutralising antibodies. The mutations present in spike also involve key structural epitopes targeted by several monoclonal antibodies in current clinical use. Of these, seven bind to the RBM (bamlanivimab, cilgavimab, casirivimab, etesevimab, imdevimab, regdanvimab and tixagevimab) and neutralisation of Omicron has been shown to be negligible or absent. An eighth mAb, sotrovimab, targets a conserved epitope common to SARS-CoV-1 and SARS-CoV-2 outside the RBM and has only a small reduction (x3) in neutralisation potency.27–29 Two mutations at the furin cleavage site (N679K and P681H) are individually predicted to increase furin cleavage, although the combination of these changes and an adjacent change with unknown function (H655Y, also present in the Gamma VOC) is unknown.

Emergence of the Omicron variant in the UK

Despite high vaccination rates and levels of natural immunity following previous exposure in the UK, the Omicron variant has rapidly become dominant. The evolutionary relationships of SARS-CoV-2 variants at a global level are shown in Fig. 1C. The first 8 cases of Omicron were detected in the UK on the 27th and 28th November 2021 (2 in England and 6 in Scotland). Due to the rapid spread of Omicron, early genome sequences were highly related with an average genetic divergence between 1 and 7 single nucleotide polymorphisms (SNPs) (Fig. 1D). The phylogenetic relationship to Omicron sequences from other countries was consistent with multiple introductions associated with travel to South Africa followed by community transmission (discussed further in Supplementary Information). Within Scotland, 111 cases were detected in the first 10 days of the outbreak, spread across 9 separate Health Boards, the majority in NHS Greater Glasgow & Clyde (NHS GG&C).
Figure 1 - Spike amino acid changes typifying the Omicron variant. (A) Spike homotrimer in open conformation with locations of Omicron amino acid substitutions, deletions (Δ), or insertions (ins) highlighted as spheres with opaque surface representation. Colouring highlights mutations at residues with substitutions impacting RBD-specific antibodies of classes 1 (green), 2 (yellow), and 3 (blue)30, or that belong to the NTD antibody supersite (magenta)11, or that belong to the FCS (orange), with the remainder in grey. These are annotated on the monomer with an ‘up’ receptor-binding domain. The substitution D614G which is shared by common descent by all lineage B.1 descendants is italicised. The visualisation is made using a complete spike model31 which is in turn based upon a partial cryo-EM structure (RCSB Protein Data Bank (PDB) ID: 6VSB32). (B) Aligned heatmaps showing properties of amino acid residues or of the specific amino acid substitution present in the Omicron variant, as appropriate (insertion not shown). Structure-based epitope scores33 for residues in the structure of the original genotype spike in closed and open conformations are shown. For RBD residues, the results of deep mutational scanning (DMS) studies show the escape fraction (that is, a quantitative measure of the extent to which a mutation reduced polyclonal antibody binding) for each mutant averaged across plasma (‘plasma average’) and for the most sensitive plasma (‘plasma max’).36 Each mutation is classified as having evidence for mutations affecting neutralisation by either mAbs11,12,26-36 or antibodies in convalescent plasma from previously infected or vaccinated individuals26,35–37. Membership of the furin cleavage site is shown. The distance to ACE2-contacting residues that form the receptor-binding site (RBS) is shown (RBS defined as residues with an atom <4Å of an ACE2 atom in the structure of RBD bound to ACE2 (RCSB PDB ID: 6M0J 38). Finally, ACE2 binding scores representing the binding constant (Δlog10 KD) relative to the wild-type reference amino acid from DMS experiments39. (C) Inferred evolutionary relationships of SARS-CoV-2 from NextStrain (https://nextstrain.org/ncov/gisaid/global) with the Variants of Concern labelled. The colours of the tree tips correspond to the number of mutations causing Spike amino acid substitutions relative to the SARS-CoV-2 original genotype (OG) reference strain Wuhan-Hu-1. (D) Inferred evolutionary relationships of the first 111 Omicron sequences in Scotland with NHS Scottish Health boards denoted: AA, Ayrshire and Arran; FF, Fife; FV, Forth Valley; GC, Great Glasgow and Clyde; GR, Grampian; HG, Highlands; LN, Lanarkshire; LO, Lothian; TY, Tayside, see key.

Neutralising responses to Omicron (BA.1) are substantially reduced following double and partially restored following triple vaccination

Levels of neutralising antibodies in patient sera correlate strongly with protection from infection40–43, and reductions in neutralising activity against the Alpha and Delta variants are consistent with an observed reduction in vaccine effectiveness2–5,44. To investigate the likely effect of the mutations in the Omicron spike glycoprotein on vaccine effectiveness, sera collected from healthy volunteers at more than 14 days post-2nd dose vaccination with either BNT162b2, ChAdOx1 or mRNA-1273 were sorted into three age-matched groups (n=24 per group, mean age 45 years). Sera were first screened by electrochemiluminescence (MSD-ECL) assay for reactivity with SARS-CoV-2 antigens (Spike, RBD, NTD or nucleoprotein (N)). The antibody responses to RBD and NTD were significantly higher (p<0.0001) in the sera from individuals vaccinated with BNT162b2 or mRNA-1273 in comparison with the ChAdOx1 vaccinees (Fig. 2A, Supp. Table S1). In contrast, antibody responses to endemic human coronaviruses (HCoVs) (Supp. Fig. S1, Supp. Table S2) or influenza (Supp. Fig. S2, Supp. Table S3) were
similar, with the exception of coronavirus OC43, where responses in BNT162b2 and ChAdOx1 vaccinees differed significantly, perhaps suggesting modulation (back-boosting) of pre-existing OC43 responses by BNT162b2 vaccination.

Next, the neutralising antibody responses against SARS-CoV-2 pseudotypes expressing the spike glycoprotein from either Wuhan-Hu-1, or Omicron (BA.1) were compared (Fig. 3B). Vaccination with mRNA-1273 elicited the highest neutralising antibody titres (mean titre Wuhan=21,118, Omicron=285), in comparison with those elicited by vaccination with either BNT162b2 (Wuhan=4978, Omicron=148.3) or ChAdOx1 (Wuhan=882.3, Omicron=61.9). Neutralising antibody titres against Wuhan differed significantly between the three study groups. Activity against Omicron was markedly reduced in comparison with Wuhan, reduced by 33-fold for BNT162b2, 14-fold for ChAdOx1 and 74-fold for mRNA-1273 (Supp. Table S4). While the fold change in neutralisation was lowest in recipients of the ChAdOx1 vaccine and highest in recipients of the mRNA-1273 vaccine, absolute neutralisation values were highest in mRNA-1273 followed by BNT162b2 and ChAdOx1. Neutralisation was lowest in the ChAdOx1 group, however it is important to note that this was given to older patients during early vaccine rollout in the UK, especially to vulnerable patients in nursing homes and was not recommended in young adults less than 40 years.

Figure 2 - Antibody responses elicited by two doses of SARS-CoV-2 vaccine. Antibody responses were studied in three groups of individuals (n=24 per group) vaccinated with either BNT162b2, ChAdOx1 or mRNA-1273 by (A) MSD-ECL assay or (B) pseudotype-based neutralisation assay. (A) Responses were measured against full-length spike glycoprotein (Spike), receptor binding domain (RBD), N-terminal domain (NTD) and nucleoprotein (N) and are expressed as arbitrary units (AU/ml).
Neutralising antibody responses were quantified against Wuhan or Omicron spike glycoprotein bearing HIV(SARS-CoV-2) pseudotypes. Each point represents the mean of three replicates, bar represents the group mean. In panel B, % neutralising refers to the % of serum samples that displayed neutralising activity.

Next, samples were analysed from vaccine recipients at least 14 days post booster vaccination (third dose). Participants had been primed with two doses of either ChAdOx1 or BNT162b2, followed by a third dose of either BNT162b2 or mRNA-1273 (half dose; 50µg). All sera reacted strongly with SARS-CoV-2 antigens by MSD-ECL, with no significant differences between the four groups (Fig. 3A, Supp. Table S5). Antibody responses to HCoVs (Supp. Fig. S3, Supp. Table S6) or influenza (Supp. Fig. S4, Supp. Table S7) were similar, with the exception of influenza Michigan H1, where responses in ChAdOx1-primed and BNT162b2 or mRNA-1273-boosted groups differed significantly, likely reflecting co-administration of influenza booster vaccines during the booster campaign. Two vaccine recipients boosted with BNT162b2 displayed weak reactivity with nucleocapsid (Fig. 3A), suggesting previously undetected exposure to SARS-CoV-2. Sera from vaccine recipients primed with BNT162b2 and boosted with either BNT162b2 or mRNA-1273 displayed similar titres of neutralising antibody against Wuhan to the samples collected post-dose 2 (Fig. 3B). In contrast, vaccination of individuals primed with ChAdOx1 with a booster dose of either BNT162b2 or mRNA-1273 resulted in a marked increase in antibody titre (9.3-fold increase) against Wuhan relative to the low titres after dose 2 (Fig. 3B, Supp. Table S8). The marked increase in antibody titre in ChAdOx1-primed individuals (Supp. Fig. S5) emphasises the importance of the third dose booster in this population. Indeed, following boost with either BNT162b2 or mRNA-1273, anti-Wuhan neutralising antibody titres in the ChAdOx1-primed group were not significantly different from those primed with BNT162b2 (Supp. Table S8).

Neutralising antibody titres against Omicron were lower in both booster study groups and did not differ significantly in titre (Supp. Table S8). However, absolute numbers displaying measurable Omicron neutralising activity were higher in the ChAdOx1-primed group (13/21, 62%) compared with the BNT162p2 primed group (5/20, 25%) (Fig. 3B).
Figure 3 - Antibody responses elicited by SARS-CoV-2 booster vaccines. Antibody responses were studied in two groups of individuals primed with two doses of either BNT162b2 or ChAdOx1 and boosted with either BNT162b2 or mRNA-1273. Reactivity against SARS-CoV-2 antigens was measured by (A) MSD-ECL assay while neutralising activity (B) was measured using HIV (SARS-CoV-2) pseudotypes. (A) Responses were measured against full-length spike glycoprotein (Spike), receptor binding domain (RBD), N-terminal domain (NTD) and nucleoprotein (N) and are expressed as arbitrary units (AU/ml). (B) Neutralising antibody responses were quantified against Wuhan or Omicron spike glycoprotein-bearing HIV (SARS-CoV-2) pseudotypes. Each point represents the mean of three replicates, bar represents the group mean. Dose 3 sera from mRNA-1273 booster are in red, while those from BNT162b2 booster are in yellow. Fold changes between marked groups are indicated.

Vaccine effectiveness against infection with the Omicron variant is reduced compared to Delta

We next used a logistic additive model with a test negative case control design to estimate relative vaccine effectiveness against becoming a confirmed case with Delta (2553 cases) and/or Omicron (1001 cases) in a population of 1.2 million people in the largest health board in Scotland, NHS GG&C, between 6th - 12th December 2021. Demographic data is shown in Supp.Table S9 and Supp.Fig.S6. The timing of first doses of vaccination are shown in Fig.4A and the occurrence of sequenced/confirmed infections with different variants in vaccine recipients over time is shown in Fig.4B. Infection status for Omicron and Delta was modelled by number and product type of vaccine doses, previous infection status, sex, SIMD quartile, and age (to control for demographic bias). We ran two models, one with time since vaccination included, to estimate the protection provided by recent vaccination, and one without, to observe the current protection in today’s mixed and waned population. Immunosuppressed individuals were removed from the analysis to ensure case-positivity could be
attributed to vaccine escape rather than an inability to mount a vaccine response. Age and time since vaccination were each modelled as single smooth effects using thin plate regression splines\textsuperscript{45}.

In both models, we estimated the protection from vaccine-acquired and infection-acquired immunity as being markedly reduced against Omicron compared with Delta. Estimates of vaccine effectiveness in recent recipients (at 14 days post-dose) were negative for full primary courses of ChAdOx1 against Omicron and only 16\% against Delta. For two doses of mRNA vaccines, vaccine effectiveness was significantly lower for Omicron versus Delta; BNT162b2 (6.84\% versus 56.53\%) and mRNA-1273 (8.83\% versus 60.07\%) (Fig.4C). These responses increased significantly following a third booster dose of BNT162b2 or mRNA-1273 to 91.87\% and 89.28\% against Delta and 67.57\% and 71.15\% against Omicron. These estimates are similar to those reported against symptomatic infection recently in England where vaccine effectiveness was estimated as 71.4\% and 75.5\% for ChAdOx1 and BNT162b2 primary course recipients boosted with BNT162b2, respectively\textsuperscript{18}.

Our estimates of protection in the current GG&C cohort, whose median time since most recent dose is 5 months, were notably lower (Fig.4D). This waning of protection was evident for both variants, leading to very low levels of protection against Omicron in double vaccine recipients of ChAdOx1, BNT162b2 and mRNA-1273 (5.19\%, 24.39\% and 24.86\% respectively). Our estimates for current protection against Omicron in recipients of a third booster dose of BNT162b2 or mRNA-1273 were much higher at 59.21\% and 64.9\%.

We next estimated the additive protective effect of previous natural infection. Infection-acquired immunity directed against other VOCs may be broader in nature and may wane more slowly than that induced by vaccines\textsuperscript{46–48}. The level of protection following previous infection was 53.2\% for Omicron, and 88.7\% for Delta. This level of protection was greater than two doses of vaccine but did not reach levels attained by those who had never had natural infection and had received third dose boosters. These results collectively emphasise the importance of booster vaccines. The observation of waning protection indicates that in due course these may need to be repeated. Importantly, vaccine-mediated protection against severe disease is likely to be more durable than that against detected infection\textsuperscript{49}.
Figure 4 - Vaccine deployment and vaccine effectiveness estimates. (A) Date of first administered vaccine dose by vaccine product for the population of NHS Greater Glasgow and Clyde (NHS GG&C) aged 18 and older. (B) Denominator plot showing populations of test positive and test negative cohorts in NHS GG&C, with VOC classification of sequenced cases overlaid. The widths of the grey bands represent the populations in each group at each time point. (C) and (D) Estimated vaccine effectiveness against testing positive for Delta and Omicron SARS-CoV-2 infection in the population of over 18s in NHS GG&C who were tested between 6th and 12th December 2021, with the waning effect of vaccination over time excluded (C) and included (D). The additive effect of infection-acquired immunity was calculated for the entire population and plotted for the unvaccinated cohort. *The interval estimate for vaccine effectiveness against Omicron for two doses of ChAdOx1 was negative (CI: -74.2% to -16.1%) for the model without the waning effect of vaccination.
Isolation of SARS-CoV-2 Omicron from clinical samples.

We obtained nasopharyngeal swabs from 5 patients who were confirmed to be PCR-positive for infection with the SARS-CoV-2 Omicron variant. We attempted virus isolation in BHK-21 cells stably expressing the human ACE2 protein (BHK-hACE2) and VERO cells stably expressing ACE2 and TMPRSS2 (VAT69). The infected cells were incubated at 37°C and the cells monitored for signs of cytopathic effect (CPE) and the presence of viral progeny in the medium by RT-qPCR. While we observed no CPE in any of the infected cells, by RT-qPCR data at 5 days post-infection (dpi) we confirmed the presence of the virus derived from two of the five samples (referred from now on as 204 and 205) only in the medium of BHK-hACE2, but not VAT cells (Supp.Fig. S7A). An aliquot of the clarified medium containing approximately 4x10^4 viral genomes of the P0 stocks of samples 204 and 205 was used to infect VAT, BHK-Ace2 and Calu-3 cells. Again, no CPE was observed in any of the infected cells but virus replication was confirmed in BHK-Ace2 and Calu-3 by RT-qPCR. Supernatants (termed P1) from infected Calu-3 cells at 3 dpi were collected and virus titrated by both focus forming assay and RT-qPCR. We found that the virus reached more than 100-fold higher titres in Calu-3 cells compared to BHK-hACE2 (Supp.Fig. S7B). Further passage of sample 205-derived P1 virus in both Calu-3 and Caco-2 yielded equivalent genome copy numbers in both cell lines (Supp.Fig. S7B). We observed CPE at 3 dpi in both Calu-3 and Caco2 cells (not shown). The medium (termed P2) of infected Calu-3 and Caco2 cells was collected at 4 dpi, titrated and used in the experiments described below.

Omicron does not induce cell syncytia

Our data demonstrate that antigenic change in Omicron permits evasion of vaccine induced immunity, however, the constellation of spike mutations in Omicron suggest that functional change may also contribute to its rapid transmission (Fig.1A). Therefore, we investigated the virological properties of live Omicron isolated from a patient sample. SARS-CoV-2 particles can achieve membrane fusion at the cell surface following proteolytic activation of spike by the plasma membrane protease TMPRSS2. This property also permits spike-mediated fusion of SARS-CoV-2 infected cells with adjacent cells resulting in syncytia50; this feature has been associated with severe disease51. The SARS-CoV-2 Delta variant has been shown to exhibit enhanced fusion compared to the Alpha and Beta variants52. We used the split GFP cell-cell fusion system53 to quantify virus-induced cell fusion by Omicron, Delta and first wave Wuhan D614G virus (Fig. 5A). Cells expressing split GFP were infected with SARS-CoV-2 Wuhan-D614G, Delta or Omicron and the levels of the reconstituted GFP signal following cell-cell fusion was determined in real time (Fig. 5B). In addition, infected cells were probed by indirect immunofluorescence assay to assess viral replication by the detection of the viral nucleocapsid protein (Fig. 5C). The Delta variant exhibited the highest levels of cell fusion followed by Wuhan D614G.
Interestingly, the Omicron variant failed to promote fusion. This failure was not due to lack of infection as immunofluorescent detection of nucleocapsid protein confirmed viral replication by Omicron, as well as the other two variants. By immunofluorescence, syncytia were clearly evident in Wuhan D614G and Delta-infected cells, consistent with other recent reports25.

**Reduced replication kinetics of Omicron in lung epithelial cells**

We next tested virus replication of Omicron, compared to Delta and Wuhan D614G in Calu-3, a human lung epithelial cell line. As shown in Fig. 5D, Wuhan D614G and Delta displayed comparable replication kinetics over a period of 72 hours, with visible CPE between 48-72hpi. The titres of the Omicron variant were instead at least an order of magnitude lower at each time point compared to the other two variants. This is consistent with attenuated replication of Omicron in lower respiratory tissues as recently reported25,54.
Figure 5. Reduced fusogenicity and replication kinetics by Omicron. A. Schematic representation of the split GFP system, used in this study to quantify virus induced cell fusion. This system is based on co-culture of two different cell lines (GFP-10 and GFP-11) expressing split GFP molecules. Upon virus-induced cell fusion, the intact GFP molecule is reconstituted and the resulting signal can be detected and quantified. B. GFP-10 and GFP-11 were co-cultured and infected with Wuhan D614G, Delta and Omicron and incubated in a CLARIOStar Plus (BMG LABTECH) at 37°C / 5% CO₂. GFP signal was measured every 30 min for 20h. Omicron infected cells showed only background levels of GFP signal. C. GFP-10 and GFP-11 infected cells were also analysed in parallel by immunofluorescence at 22h post-infection. Virus replication was assessed by detecting viral
nucleocapsid (N) expression using the appropriate antiserum and secondary antibodies. N expression can be detected in both Wuhan D614G, Delta and Omicron infected cells. However, syncytia can only be observed in Wuhan (D614G) and Delta infected cells. D. Replication kinetics of Wuhan D614G, Delta and Omicron. Calu-3 cells were infected with Wuhan D614G, Delta and Omicron and supernatants were collected at the indicated times and assessed by RT-qPCR. Omicron display reduced replication kinetics compared to Wuhan D614G and Omicron.
**Omicron spike has switched entry route preference**

Entry of SARS-CoV-2, and related coronaviruses, can proceed via two routes\(^{55}\). Cell surface fusion following proteolysis by TMPRSS2, as described above (Route 1; **Fig. 6A**), or fusion from the endosome after endocytosis and activation by the endosomal proteases Cathepsin B or L (Route 2; **Fig. 6A**). The ability of SARS-CoV-2 to achieve cell surface fusion is dependent on its S1/S2 polybasic cleavage site; this is absent from most closely related sarbecoviruses, which are confined to endosomal fusion\(^{56–58}\).

Given the reduced fusogenicity and replication kinetics of Omicron, we used HIV pseudotypes to evaluate entry route preference. We evaluated Wuhan D614G, Alpha, Delta and Omicron spike and as a control we included Pangolin CoV (Guangdong isolate) spike, which exhibits high affinity interactions with human ACE2 but lacks a polybasic cleavage site and, therefore, enters via the endosome only\(^{59–62}\).

Calu-3 cells predominantly support cell surface (Route 1) fusion, owing to their high endogenous expression of TMPRSS2\(^{57,63}\); in these cells, Delta yielded the highest infection, being ~4 fold higher than Omicron (**Fig. 6B**). Pangolin CoV infection was low, indicating that Calu-3 cells do not support robust endosomal entry. On the contrary, HEK only support endosomal entry and in these cells Pangolin CoV had high infection. Notably, Omicron also achieved high infection in HEK cells, producing ~10 fold greater signal than Delta. This suggests that Omicron, like Pangolin CoV, is optimised for endosomal entry. All pseudotypes exhibited robust infection in A549 ACE2 TMPRSS2, where both entry routes are available\(^{64,65}\).

Entry pathway preference was further investigated using protease inhibitors targeting either TMPRSS2 (Camostat) or cathepsins (E64d)\(^{58}\). In Calu-3 cells, all SARS-CoV-2 pseudotypes were inhibited by Camostat, whereas only Omicron exhibited E64d sensitivity, indicating that a component of infection occurs via endosomal entry (**Fig. 6C**). In HEK cells all pseudotypes were inhibited by E64d, whereas Camostat was non-inhibitory; this confirms that only endosomal entry is available in these cells.

Inhibitor treatment in A549 ACE2 TMPRSS2 provided the clearest evidence of altered entry by Omicron. D614G, Alpha and Delta were potently inhibited by Camostat, but not E64d. For Omicron, and Pangolin CoV, this pattern was completely reversed, suggesting a binary switch from cell surface to endosomal fusion; this conclusion was supported by titration of either inhibitor in A549 ACE2 TMPRSS2 cells (**Fig. 6D**).

These data indicate that, whilst Delta is optimised for fusion at the cell surface, Omicron preferentially achieves entry through endosomal fusion; this biological about-face may impact transmission, cellular tropism and pathogenesis. Moreover, this switch away from TMPRSS2-mediated activation offers a mechanistic explanation for reduced syncytia formation by Omicron infected cells.
Figure 6. Omicron spike has switched entry route preference. A. SARS-CoV-2 entry can occur via two routes. Route 1 permits rapid fusion at the cell surface following proteolytic processing by TMPRSS2. In Route 2 fusion occurs following endocytosis after processing by cathepsins B or L. Route 1 and 2 can be specifically inhibited using the protease inhibitors Camostat and E64d, respectively. B. SARS-CoV-2 pseudotype infection of the stated cell lines, data represent mean luciferase values from one representative experiment. In Calu-3 cells Route 1 entry predominates whereas HEK exclusively support Route 2, A549 ACE2 TMPRSS2 cells permit both routes. Pangolin CoV spike is included as a control; it can only achieve entry via Route 2. Pseudotypes without viral glycoproteins (No) are included as a negative control. C. Relative SARS-CoV-2 pseudotype infection (compared to untreated control) of cells treated with 10µM protease inhibitors. Data represent mean of four replicates, error bars indicate standard error of the mean, asterisks indicate statistical significance (ANOVA). D. Titration of Camostat and E64d against Delta, Omicron and Pangolin CoV in A549 ACE2 TMPRSS2 cells, data points represent mean relative infection, compared to untreated control.
Conclusions

The Omicron variant represents a major change in biological function and antigenicity of SARS-CoV-2 virus. In this study, we demonstrate substantial immune escape of this variant with clear evidence of vaccine failure in dual vaccinated individuals and partial restoration of immunity following a third booster dose of mRNA vaccine. In addition, we demonstrate a shift in the SARS-CoV-2 entry pathway from cell surface fusion, triggered by TMPRSS2, to cathepsin-dependent fusion within the endosome. This fundamental biological shift may affect the pathogenesis and severity of disease and requires further evaluation in population-based studies.

Using sera from double vaccine recipients, we found that Omicron is associated with a drop in neutralisation greater in magnitude than that reported in all other variants of concern (including Beta and Delta). Boosting enhanced neutralising responses to both Wu-Hu-1 and Omicron, particularly in recipients of ChAdOx1, but did not completely overcome the inherent immune escape properties of Omicron. Importantly, we did not assess the impact of vaccination on clinical severity of disease which is likely to be much higher than detection of infection. Protection against severe disease is longer lasting than prevention of infection. We also did not measure the impact of vaccination on T cell immunity which may be better preserved as only 14% of CD8+ and 28% of CD4+ epitopes are predicted to be affected by key Omicron mutations.

In order to evaluate the impact of reduced neutralisation responses in vaccine recipients, we next assessed vaccine effectiveness. The probability of infection with Omicron versus the preceding Delta variant was significantly higher in double vaccine recipients, in keeping with the neutralisation data. A third dose of mRNA vaccine substantially reduced the probability of infection but did not restore immunity fully.

The observation of a highly transmissible variant that is associated with escape from vaccine-induced immune responses means that over time, Omicron-specific vaccines would be required if disease severity was high, either directed at the general population or vulnerable groups. Early indications in young people are that Omicron is 40-70% less severe than Delta – similar calculations in the most vulnerable part of the population over the age of 40 years are awaited.

Genotypic change in new variants have previously been shown to alter viral phenotype by modulating innate immune responses as well as evasion of the adaptive immune response. Additionally, mutations can alter spike functionality to impact transmission and pathogenesis. For example, a polybasic insertion at the S1/S2 spike junction that facilitates cleavage of the spike glycoprotein by furin during virus assembly. This may have provided a selective advantage in lung cells and primary
human airway epithelial cells for the original emergent SARS-CoV-2, and previous VOCs by permitting spike activation by the plasma membrane protease TMPRSS2, enabling rapid cell surface fusion. In this study, we found that the Omicron variant has switched entry pathway to preferentially use endosomal fusion that is independent of TMPRSS2; a major change in the biological behaviour of the virus. This switching in the mechanism of fusion activation also manifests in reduced syncytia formation in infected cells, likely to reduce the cell-to-cell transmission characteristic of other variants. These properties have the potential to substantially change cellular tropism and pathogenesis of disease. Nonetheless, even a variant that is less virulent with a very high transmission rate may still present a substantial risk to older people and those with co-morbidities, especially those with immunosuppression. Moreover, our work demonstrates that SARS-CoV-2 exhibits high antigenic and functional plasticity; further fundamental shifts in transmission and disease should be anticipated.

Methods

Cells. Calu-3 are human lung adenocarcinoma epithelial cells. Caco-2 are an immortalized cell line derived from human colorectal adenocarcinoma, primarily used as a model of the intestinal epithelial barrier. A549 cells, a human alveolar adenocarcinoma line, were modified to stably express human ACE-2 and TMPRSS2. Human embryonic kidney (HEK293T) cells were used in pseudotype production. Baby Hamster Kidney clone 21 cells and Vero ACE-2 TMPRSS2 cells were used in the isolation of live Omicron SARS-CoV-2. All cell lines were maintained at 37°C and 5% CO_2 in DMEM supplemented with 10% foetal bovine serum (FBS), except for Calu-3 cells which were supplemented with 20% FBS.

Generation of cell line expressing human ACE2 receptor. Lentiviral vectors encoding human ACE2 (GenBank NM_001371415.1) were produced as described previously and BHK-21 transduced cells were selected with 200µg/ml of hygromycin B.

Generation of cell lines used for fusion assays. Retrovirus vectors were produced by transfecting HEK-293T cells with plasmid pQCXIP-GFP1-10 (Addgene #68715) or pQCXIP-BSR-GFP11 (Addgene #68716) and packaging vectors expressing MLV gal-pol and VSV-G using Lipofectamine 3000 (Invitrogen) according to manufacturer’s instructions. Cell supernatants were harvested 24-48h post-transfection, pooled, clarified by centrifugation and filtered. One mL of each supernatant was used to transduce A549-Ace2-TMPRSS2 (AAT) cells in presence of Polybrene (Merck). Two days post-transduction, the supernatant was replaced with selection medium (DMEM 10% FBS 1µg/mL puromycin) and cells incubated until complete death of the untrasduced control cells were observed. The resulting puromycin-resistant cells (termed AAT-GFP1-10 and AAT-BSR-GFP11) were used in fusion assays.
Virus isolation from clinical sample. Nasopharyngeal swabs of patients infected with Omicron were collected with biorepository ethical approval (reference 10/S1402/33) in virus transport medium and resuspended in serum-free DMEM supplemented with 10 µg/ml gentamicin, 100 units/ml penicillin-streptomycin and 2.5µg/ml amphotericin B to a final volume of 1.5ml. BHK-hACE2 cells previously seeded at a cell density of 3x10^5 cells in T25 flask were inoculated with 400-500µL of resuspended samples in 5ml of complete medium (DMEM 2% FCS supplemented with gentamicin, penicillin-streptomycin and amphotericin B as above). After 20 hours, medium was replaced with fresh complete medium. Virus replication was monitored and confirmed over time by RT-qPCR since no clear cytopathic effect was observed. Culture supernatants (defined as P0) were harvested at day 4 post-infection. The P0 supernatant was next passaged in Calu-3 cells and after 3-4 days post-infection supernatant (P1) was harvested and stored at -80°C after clarification (500g x 10min) and used as working stock.

Measurement of SARS-CoV-2, HCoVs and influenza antibody response by electrochemiluminescence. IgG antibody titres were measured quantitatively against SARS-CoV-2 trimeric spike (S) protein, N-terminal domain (NTD), receptor binding domain (RBD) or nucleocapsid (N), human seasonal coronaviruses (HCoVs) 229E, OC43, NL63 and HKU1; and influenza A (Michigan H1, Hong Kong H3 and Shanghai H7) and B (Phuket HA and Brisbane) using MSD V-PLEX COVID-19 Coronavirus Panel 2 (K15369) and Respiratory Panel 1 (K15365) kits. Multiplex Meso Scale Discovery electrochemiluminescence (MSD-ECL) assays were performed according to manufacturer instructions. Briefly, 96-well plates were blocked for one hour. Plates were then washed, samples were diluted 1:5000 in diluent and added to the plates along with serially diluted reference standard (calibrator) and serology controls 1.1, 1.2 and 1.3. After incubation, plates were washed and SULFO-TAG detection antibody added. Plates were washed and were immediately read using a MESO Sector S 600 plate reader. Data were generated by Methodological Mind software and analysed using MSD Discovery Workbench (v4.0). Results are expressed as MSD arbitrary units per ml (AU/ml). Reference plasma samples yielded the following values: negative pool - spike 56.6 AU/ml, NTD 119.4 AU/ml, RBD 110.5 AU/ml and nucleocapsid 20.7 AU/ml; SARS-CoV-2 positive pool - spike 1331.1 AU/ml, NTD 1545.2 AU/ml, RBD 1156.4 AU/ml and nucleocapsid 1549.0 AU/ml; NIBSC 20/130 reference - spike 547.7 AU/ml, NTD 538.8 AU/ml, RBD 536.9 AU/ml and nucleocapsid 1840.2 AU/ml.

Measurement of virus neutralising antibodies using viral pseudotypes. Pseudotype-based neutralisation assays were carried out as described previously2,69,70. Briefly, HEK293, HEK293T, and 293-ACE269 cells were maintained in Dulbecco’s modified Eagle’s medium (DMEM) supplemented
with 10% FBS, 200mM L-glutamine, 100µg/ml streptomycin and 100 IU/ml penicillin. HEK293T cells were transfected with the appropriate SARS-CoV-2 S gene expression vector (wild type or variant) in conjunction with p8.9171 and pCSFLW72 using polyethyleneimine (PEI, Polysciences, Warrington, USA). HIV (SARS-CoV-2) pseudotypes containing supernatants were harvested 48 hours post-transfection, aliquoted and frozen at -80°C prior to use. S gene constructs bearing the WUHAN (D614G) and Omicron (B.1.1.529) S genes were based on the codon-optimised spike sequence of SARS-CoV-2 and generated by GeneArt (ThermoFisher). Constructs bore the following mutations relative to the Wuhan-Hu-1 sequence (GenBank: MN908947): WUHAN(D614G) – D614G; Omicron (BA.1, B.1.1.529) - A67V, Δ69-70, T95I, G142D/Δ143-145, Δ211/L212I, ins214EPE, G339D, S371L, S373P, S375F, K417N, N440K, G446S, S477N, T478K, E484A, Q493R, G496S, S477N, T478K, D614G, H655Y, N679K, P681H, N764K, D796Y, N856K, Q954H, N969K, L981F. 293-ACE2 target cells were maintained in complete DMEM supplemented with 2µg/ml puromycin.

Neutralising activity in each sample was measured by a serial dilution approach. Each sample was serially diluted in triplicate from 1:50 to 1:36450 in complete DMEM prior to incubation with HIV (SARS-CoV-2) pseudotypes, incubated for 1 hour, and plated onto 239-ACE2 target cells. After 48-72 hours, luciferase activity was quantified by the addition of Steadylite Plus chemiluminescence substrate and analysis on a Perkin Elmer EnSight multimode plate reader (Perkin Elmer, Beaconsfield, UK). Antibody titre was then estimated by interpolating the point at which infectivity had been reduced to 50% of the value for the no serum control samples.

**Protease inhibitor studies.** To selectively inhibit either cell surface or endosomal fusion of SARS-CoV-2, cells were pre-treated for one hour with 10µM of either Camostat mesylate (referred to hence forth as Camostat) or E64d prior to inoculation with pseudotype. In these studies, spike proteins from Alpha and Delta VOCs, and Guangdong isolate Pangolin coronavirus (GISAID ref EPI_ISL_410721) were used as controls.

**Viral RNA extraction and RT-qPCR.** Viral RNA was extracted from culture supernatants using the RNAdvance Blood kit (Beckman Coulter Life Sciences) following the manufacturer’s recommendations. RNA was used as template to detect and quantify viral genomes by duplex RT-qPCR using a Luna® Universal Probe One-Step RT-qPCR Kit (New England Biolabs, E3006E). SARS-CoV-2 specific RNAs were detected by targeting the N1 gene from the CDC panel as part of the SARS-CoV-2 Research Use Only qPCR Probe Kit (Integrated DNA Technologies) and the ORF1ab gene using the following set of primers and probes: SARS-CoV-2_Orf1ab_Forward 5’ GACATAGAAGTTACTGG&CGATAG 3’, SARS-CoV-2_Orf1ab_Reverse 5’ TTAATATGACGCGCUCTACAG 3’, SARS-CoV-2_Orf1ab_Probe ACCCCGTGACCTTGGTCTTGTTG with HEX/ZEN/3IABkFQ modifications. SARS-CoV-2 RNA was used to
generate a standard curve and viral genomes were quantified and expressed as number of Orf1ab RNA molecules /ml of supernatant. All runs were performed on the ABI7500 Fast instrument and results analysed with the 7500 Software v2.3 (Applied Biosystems, Life Technologies).

**Genome Sequencing and analysis.** Sequencing was carried out by the UK public health agencies (UKHSA/PHE, PHS, PHW and PHNI) and by members of the COG-UK consortium using the ARTIC protocol as previously described.

Sequences were aligned by mapping to the SARS-CoV-2 reference Wuhan-Hu-1 using Minimap2 (https://doi.org/10.1093/bioinformatics/bty191). Prior to phylogenetic analysis 85 sites exhibiting high genetic variability due to data quality issues in overseas sequencing labs were excluded using a masking script in Phylopipe (https://github.com/cov-ert/phylopipe). The phylogenetic tree was constructed with the maximum likelihood method FastTree2 (https://doi.org/10.1371/journal.pone.0009490) using a JC+CAT nucleotide substitution model.

**Replication curve.** Calu-3 cells were seeded in a 96-well plate at a cell density of 3.5x10^4 cells per well. Cells were infected with the indicated viruses using the equivalent of 2x10^4 Orf1ab genome copies/well in serum-free RPMI-1640 medium (Gibco). After one hour of incubation at 37°C, cells were washed three times and left in 20% FBS RPMI-1640 medium. Supernatants were collected at different times post-infection and viral RNA extracted and quantified as described above.

**Fusion assay.** AAT-GFP1-10 and AAT-BSR-GFP11 cells were trypsinized and mixed at a ratio of 1:1 to seed a total of 2x10^4 cells/well in black 96-well plate (Greiner) in FluoroBrite DMEM medium (Thermo Fischer Scientific) supplemented with 2% FBS. Next day, cells were infected with the indicated viruses using the equivalent of 10^6 Orf1a genome copies/well in FluoroBrite DMEM 2% FBS. GFP signal was acquired for the following 20 hours using a CLARIOStar Plus (BMG LABTECH) equipped with ACU to maintain 37°C and 5% CO2. Data were analysed using MARS software and plotted with GraphPad prims 9 software. At 22 hs post-infection, cells were fixed in 8% formaldehyde, permeabilized with 0.1 % Triton X-100 and stained with sheep anti-SARS-CoV-2 N (1:500) antiserum followed by Alexa Fluor 594 Donkey anti-sheep IgG (H+L) (1:500, Invitrogen) and DAPI (1:4000, Sigma). Cell imagines were acquired using EVOS Cell Imaging Systems (Thermo Fischer Scientific).

**Demographic data.** Data for the EVADE study were available using the NHS Greater Glasgow and Clyde (NHS GG&C) SafeHaven platform and included vaccination status (dates and product names for each dose), demographic data (age, sex and Scottish Index of Multiple Deprivation (SIMD) quartile) comorbidity (shielding and immunosuppression status) and dates of positive and negative PCR tests, for 1.2 million inhabitants of the (NHS GG&C) area over 18 years of age, from 1st March 2020 up to
21st December 2021. Data were matched by CHI number and pseudonymised before analysis. Derogated ethical approval was granted by the NHS GG&C Safe Haven committee (GSH/21/IM/001).

**Vaccine effectiveness.** We used a logistic additive regression model to estimate relative vaccine effectiveness against the Omicron variant as it emerged in a population of 1.2 million people in NHS Greater Glasgow & Clyde, the largest health board in Scotland. Infection status for Omicron and Delta was modelled by number and product type of vaccine doses, previous infection status, sex, SIMD quartile, age on 31st October 2021 and time since most recent vaccination.

We identified Omicron infections using 3 data streams: confirmed S gene target failure (SGTF), allele specific PCR, and Pango lineage assignments from the sequencing data. SGTF samples with Delta lineage assignments were assigned as Delta infections. Samples for which the sequencing date was more than two weeks away from the first positive PCR were removed from the analysis.

We removed a small number of individuals who received ChAdOx1 as a third dose or had their third dose before the first of September 2021 on the assumption that the majority were part of the COV-BOOST clinical trial, the results of which are published elsewhere. We removed anyone with ambiguous vaccination status or whose brand was unknown due to data entry error.

**Serum samples.** Serum samples were collected from healthy participants in the COVID-19 Deployed Vaccine Cohort Study (DOVE), a cross-sectional post-licensing cohort study to determine the immunogenicity of deployed COVID-19 vaccines against evolving SARS-CoV-2 variants. 308 adult volunteers aged at least 18 years and were recruited into the study 14 days or more after a second or third dose of vaccine. All participants gave written informed consent to take part in the study. The DOVE study was approved by the North-West Liverpool Central Research Ethics Committee (REC reference 21/NW/0073).

**Structural modelling.** The file 6vsb_1_1_1.pdb containing a complete model of the full-length glycosylated spike homotrimer in open conformation with one monomer having the receptor-binding domain in the ‘up’ position was obtained from the CHARMM-GUI Archive [cite Woo et al. 2020, cite CHARMM-GUI 2021]. This model is itself generated based upon a partial spike cryo-EM structure (PDB ID: 6VSB). For visualisation, the model was trimmed to the ectodomain (residues 14-1164) and the signal peptide (residues 1-13) and glycans were removed. Using this structural model and the closed conformation equivalent (6vxx_1_1_1.pdb). Residues belonging to the receptor-binding site were identified as those with an atom within 4Å of an ACE2 atom in the bound RBD-ACE2 structure (PDB ID: 6M0J38) and Alpha carbon-to-Alpha carbon distances between these residues in the ‘up’ RBD and all
other spike residues were calculated. Antibody accessibility scores for open and closed conformations were calculated using BEpro\textsuperscript{33}. Figures were prepared using PyMol\textsuperscript{74}.

**Acknowledgments**

The authors would like to thank the participants of the DOVE study and Sister Therese McSorley and her nursing team at the NHS GG&C clinical research facility. The authors also thank Alison Hamilton, Laura Stirling and Charlie Mayor from the NHS GG&C SafeHaven team for their invaluable input in facilitating this study. We thank Paula Olmo for administrative support and Chris Robertson and Aziz Sheikh for statistical advice. The authors thank all of the researchers who have shared genome data openly via the Global Initiative on Sharing All Influenza Data (GISAID).

**Funding:** The EVADE study is supported by HDR-UK (E.C.T). COG-UK is supported by funding from the Medical Research Council (MRC) part of UK Research & Innovation (UKRI), the National Institute of Health Research (NIHR) [grant code: MC_PC_19027], and Genome Research Limited, operating as the Wellcome Sanger Institute (G.M., R.M.B., D.L.R., E.C.T.). The COVID-19 DeploOyd VaccinE (DOVE) study is funded by the Medical Research Council core award (MCUU1201412) and COG-UK. **Epidemiological description of the emergence of the Omicron variant in the UK**

On the 27th November 2021, the UK Health Security Agency detected 2 cases of Omicron in England, the following day 6 Scottish cases were detected by community (Pillar 2) sequencing. Over the next 10 days (to 8th December 2021) a further 95 genome sequences were obtained. Due to the rapid spread of Omicron and low genetic diversity, the genome sequences are highly related with mean genetic divergence of 1 single nucleotide polymorphisms (SNPs) and maximum 7 SNPs.

The phylogenetic relationship to Omicron sequences from other countries is consistent with multiple introductions associated with travel to South Africa followed by community transmissions within Scotland. Amongst the Scottish samples diverged from the tree backbone, there were a number identified that are genetically divergent, i.e., greater than 2 single nucleotide polymorphisms from the nearest Scottish sample (Figure 1D). Moreover, comparison to the wider international collection of Omicron samples revealed that they were more closely related to genomes from other countries than other Scottish samples. These samples therefore likely represent independent introductions to Scotland, but without more detailed epidemiological data, the number of introductions is unknown. Where there are indistinguishable samples in the phylogeny from Scotland and elsewhere in world, importation cannot be ruled out as a source of these samples in Scotland, rather than transmission from an established population circulating in Scotland.

Within Scotland, cases are spread across 9 separate Health Boards and distributed throughout the phylogeny (Figure 1D). Basal Scottish genomes were sampled in 7 different Health Boards, most of them from NHS Greater Glasgow & Clyde (47%) and NHS Lanarkshire (25%). Notably, amongst these earliest samples are cases that were epidemiologically linked to early spreading events. All but one of these samples were found on this basal branch and are indistinguishable, and which is consistent with transmission at these events.
Supplementary Table S1. Comparison of SARS-CoV-2 antibody responses elicited by two doses of SARS-CoV-2 vaccine. Data were analyzed in GraphPad Prism v8.4.3, groups were compared by ordinary one-way ANOVA.

Supplementary Table S8. Effect of third dose of SARS-CoV-2 vaccine on neutralising antibody titres.

Neutralising antibody responses were quantified against Wuhan or Omicron spike glycoprotein-bearing HIV (SARS-CoV-2) pseudotypes. Data were analyzed in GraphPad Prism v8.4.3, groups were compared by ordinary one-way ANOVA.

Supplementary Figure S1. HCoV reactivity following two doses of SARS-CoV-2 vaccine. Antibody responses were studied in three groups of individuals (n=24 per group) vaccinated with either BNT162b2, ChAdOx1 or mRNA-1273 by MSD-ECL assay. Responses were measured against full-length spike glycoprotein (Spike) from HCoVs 229E, OC43, NL63 and HKU1 and are expressed as MSD arbitrary units (AU/ml). The response to OC43 was significantly higher in BNT162b2 vaccinates than in ChAdOx1 vaccinates.
Supplementary Figure S2. Influenza reactivity following two doses of SARS-CoV-2 vaccine.

Antibody responses were studied in three groups of individuals (n=24 per group) vaccinated with either BNT162b2, ChAdOx1 or mRNA-1273 by MSD-ECL assay. Responses were measured against haemagglutinins from influenza viruses; influenza A Michigan H1, Hong Kong H3 and Shanghai H7, and influenza B Phuket HA and Brisbane and are expressed as MSD arbitrary units (AU/ml). No significant differences were detected between the vaccine groups for each of the antigens.
Supplementary Figure S3. HCoV reactivity following third dose of SARS-CoV-2 vaccine.
Antibody responses were studied in four groups of individuals primed with two doses of either ChAdOx1 or BNT162b2, followed by a booster of BNT162b2 or mRNA-1273. Responses were measured by MSD-ECL assay against full-length spike glycoprotein (Spike) from HCoVs 229E, OC43, NL63 and HKU1 and are expressed as MSD arbitrary units (AU/ml).
Supplementary Figure S4. Influenza reactivity following third dose of SARS-CoV-2 vaccine. Antibody responses were studied in four groups of individuals primed with two doses of either ChAdOx1 or BNT162b2, followed by a booster of BNT162b2 or mRNA-1273. Responses were measured by MSD-ECL against haemagglutinins from influenza viruses; influenza A Michigan H1, Hong Kong H3 and Shanghai H7, and influenza B Phuket HA and Brisbane and are expressed as MSD arbitrary units (AU/ml). * Significantly different p=0.0413.
Supplementary Figure S5. Effect of third dose of SARS-CoV-2 vaccine on neutralising antibody titres.

Two groups of healthy volunteers vaccinated with two doses of either ChAdOx1 or BNT162b2, were sampled two weeks following a third dose of either BNT162b2 or mRNA-1273. Each point represents the mean of three replicates. Where dose 2 and dose 3 samples were available from the same individual, points are joined by a solid line.
Supplementary Figure S6: Plots of demographics, SARS-CoV-2 positivity status and vaccination status in NHS GG&C. Demographic data for the population of 34,641 people aged 18 and over, registered as living in NHS Greater Glasgow and Clyde and tested by PCR test for SARS-CoV-2 infection between 6th and 12th December 2021, coloured by SARS-CoV-2 variant status. (A) Histogram of age; (B) Barplot of sex; (C) Barplot of SIMD (2016) quartile; (D) Barplot of date of positive SARS-CoV-2 PCR test; (E) Barplot of previous confirmed SARS-CoV-2 infection at least 90 days before most recent positive SARS-CoV-2 PCR test; (F) Barplots of most recent vaccine dose number, split by product name; (G) Barplot of most recent vaccine dose product name; (H) Barplots of time (days) since most recent vaccine dose, split by dose number and product name.
Supplementary Figure S7 Isolation of Omicron in cell culture. A. Vero ACE2 TMPRSS2 (VAT) and BHK-hACE2 cells were inoculated with diluted clinical samples. Viral progeny was quantified in the medium 5 dpi by RT-qPCR. B. Aliquots of the medium from samples named 204 and 205 were used to generate a P1 in BHK-hACE2 and Calu-3 cells and, limited to sample 205, a P2 in Calu-3 and Caco2 cells. Viral stocks were quantified by RT-qPCR.

Dr Helen Fryer 5

Sequencing and analysis, Software and analysis tools, and Visualisation:
Dr Helen Adams 4, Dr Louis du Plessis 23, Dr Rob Johnson 39, Dr William T Harvey 53, 42, Dr Joseph Hughes 53, Dr Richard J Orton 53, Dr Lewis G Spurgin 59, Dr Yann Bourgeois 81, Dr Chris Ruis 102, Áine O’Toole 104, Marina Gourtovaia 116 and Dr Theo Sanderson 116

Funding acquisition, and Leadership and supervision:
Dr Christophe Fraser 5, Dr Jonathan Edgeworth 12, Prof Judith Breuer 96, 29, Dr Stephen L Michell 105 and Prof John A Todd 115

Funding acquisition, and Project administration:
Michaela John 10 and Dr David Buck 115

Leadership and supervision, and Metadata curation:
Dr Kavitha Gajee 37 and Dr Gemma L Kay 75

Leadership and supervision, and Project administration:
Prof Sharon J Peacock 20, 70 and David Heyburn 74

Leadership and supervision, and Samples and logistics:
Katie Kitchman 37, Prof Alan McNally 43, 93, David T Pritchard 50, Dr Samir Dervisevic 58, Dr Peter Muir 70, Dr Esther Robinson 70, 35, Dr Barry B Vipond 70, Newara A Ramadan 78, Dr Christopher Jeanes 90, Danni Weldon 116, Jana Catalan 118 and Neil Jones 118

Leadership and supervision, and Sequencing and analysis:
Dr Ana da Silva Filipe 53, Dr Chris Williams 74, Marc Fuchs 77, Dr Julia Miskelly 77, Dr Aaron R Jeffries 105, Karen Oliver 116 and Dr Naomi R Park 116

Metadata curation, and Samples and logistics:
Amy Ash 4, Cherian Koshy 4, Magdalena Barrow 7, Dr Sarah L Buchan 7, Dr Anna Mantzouratou 7, Dr Gemma Clark 15, Dr Christopher W Holmes 16, Sharon Campbell 17, Thomas Davis 21, Ngee Keong Tan 22, Dr Julianne R Brown 29, Dr Kathryn A Harris 29, 2, Stephen P Kidd 33, Dr Paul R Grant 34, Dr Li Xu-McCrae 35, Dr Alison Cox 38, 63, Pinglawathe Madona 38, 63, Dr Marcus Pond 38, 63, Dr Paul A Randell 38, 63, Karen T Withell 48, Cheryl Williams 51, Dr Clive Graham 60, Rebecca Denton-Smith 62, Emma Swindells 62, Robyn Turnbull 62, Dr Tim J Sloan 67, Dr Andrew Bosworth 70, 35, Stephanie Hutchings 70, Hannah M Pymont 70, Dr Anna Casey 78, Dr Liz Ratcliffe 79, Dr Christopher R Jones 79, 105, Dr Bridget A Knight 79, 105, Dr Tanzina Haque 80, Dr Jennifer Hart 80, Dr Dianne Irish-Tavares 80, Eric Witele 80, Craig Mower 86, Louisa K Watson 86, Jennifer Collins 89, Gary Eltringham 89, Dorian Crudgington 98, Ben Macklin 98, Prof Miren Iturriza-Gomara 107, Dr Anita O Lucaci 107 and Dr Patrick C McClure 113
Metadata curation, and Sequencing and analysis:
Matthew Carlile 18, Dr Nadine Holmes 18, Dr Christopher Moore 18, Dr Nathaniel Storey 29, Dr Stefan Rooke 73, Dr Gonzalez Yebra 73, Dr Noel Craine 74, Malorie Perry 74, Dr Nabil-Fareed Alikhan 75, Dr Stephen Bridgett 77, Kate F Cook 84, Christopher Fearn 84, Dr Salman Goudarzi 84, Prof Ronan A Lyons 88, Dr Thomas Williams 104, Dr Sam T Haldenby 107, Jillian Durham 116 and Dr Steven Leonard 116

Metadata curation, and Software and analysis tools:
Robert M Davies 116

Project administration, and Samples and logistics:
Dr Rahul Batra 12, Beth Blane 20, Dr Moira J Spyer 30, 95, 96, Perminder Smith 32, 112, Mehmet Yavus 85, 109, Dr Rachel J Williams 96, Dr Adhyana IK Mahanama 97, Dr Buddhini Samaraweera 97, Sophia T Girgis 102, Samantha E Hansford 109, Dr Angie Green 115, Dr Charlotte Beaver 116, Katherine L Bellis 116, 102, Matthew J Dorman 116, Sally Kay 116, Liam Prestwood 116 and Dr Shavanthi Rajatileka 116

Project administration, and Sequencing and analysis:
Dr Joshua Quick 43

Project administration, and Software and analysis tools:
Radoslaw Poplawski 43

Samples and logistics, and Sequencing and analysis:
Dr Nicola Reynolds 8, Andrew Mack 11, Dr Arthur Morriss 11, Thomas Whalley 11, Bindi Patel 12, Dr Iliana Georgana 24, Dr Myra Hosmillo 24, Malte L Pinckert 24, Dr Joanne Stockton 43, Dr John H Henderson 65, Amy Hollis 65, Dr William Stanley 65, Dr Wen C Yew 65, Dr Richard Myers 72, Dr Alicia Thornton 72, Alexander Adams 74, Tara Annett 74, Dr Hibo Asad 74, Alec Birchley 74, Jason Coombes 74, Johnathan M Evans 74, Laia Fina 74, Bree Gatica-Wilcox 74, Lauren Gilbert 74, Lee Graham 74, Jessica Hey 74, Ember Hilvers 74, Sophie Jones 74, Hannah Jones 74, Sara Kumziene-Summerhayes 74, Dr Caomhie McKerr 74, Jessica Powell 74, Georgia Pugh 74, Sarah Taylor 74, Alexander J Trotter 75, Charlotte A Williams 96, Leanne M Kermack 102, Benjamin H Foulkes 109, Marta Gallis 109, Hailey R Hornsby 109, Stavroula F Louka 109, Dr Manoj Pohare 109, Paige Woolverton 109, Peijun Zhang 109, George MacIntyre-Cockett 115, Amy Trebes 115, Dr Robin J Moll 116, Lynne Ferguson 117, Dr Emily J Goldstein 117, Dr Alasdair Maclean 117 and Dr Rachael Tomb 117

Samples and logistics, and Software and analysis tools:
Dr Igor Starinskij 53

Sequencing and analysis, and Software and analysis tools:
Laura Thomson 5, Joel Southgate 11, 74, Dr Moritz UG Kraemer 23, Dr Jayna Raghwani 23, Dr Alex E Zarebski 23, Olivia Boyd 39, Lily Geidelberg 39, Dr Chris J Illingworth 52, Dr Chris Jackson 53, Dr David Pascall 52, Dr Sreenu Vattipally 53, Timothy M Freeman 109, Dr Sharon N Hsu 109, Dr Benjamin B Lindsey 109, Dr Keith James 116, Kevin Lewis 116, Gerry Tonkin-Hill 116 and Dr Jaime M Tovar-Corona 116

Sequencing and analysis, and Visualisation:
MacGregor Cox 20

Software and analysis tools, and Visualisation:
Dr Khalil Abudahab 14, 115, Mirko Menegazzo 14, Ben EW Taylor MEng 14, 116, Dr Corin A Yeats 14, Afrida Mukaddas 53, Derek W Wright 53, Dr Leonardo de Oliveira Martins 75, Dr Rachel Colquhoun 104, Verity
Hill 104, Dr Ben Jackson 104, Dr JT McCrone 104, Dr Nathan Medd 104, Dr Emily Scher 104 and Jon-Paul Keatley 116

Leadership and supervision:
Dr Tanya Curran 3, Dr Sian Morgan 10, Prof Patrick Maxwell 20, Prof Ken Smith 20, Dr Sahar Eldirdiri 21, Anita Kenyon 21, Prof Alison H Holmes 38, 57, Dr James R Price 38, 57, Dr Tim Wyatt 69, Dr Alison E Mather 75, Dr Timofey Skvortsov 77 and Prof John A Hartley 96

Metadata curation:
Prof Martyn Guest 11, Dr Christine Kitchen 11, Dr Ian Merrick 11, Robert Munn 11, Dr Beatrice Bertolusso 33, Dr Jessica Lynch 33, Dr Gabrielle Vernet 33, Stuart Kirk 34, Dr Elizabeth Wastnedge 56, Dr Rachael Stanley 58, Giles Idle 64, Dr Declan T Bradley 69, 77, Dr Jennifer Poyner 79 and Matilde Mori 110

Project administration:
Owen Jones 11, Victoria Wright 18, Ellena Brooks 20, Carol M Churcher 20, Mireille Fragakis 20, Dr Katerina Galai 20, 70, Dr Andrew Jermy 20, Sarah Judges 20, Georgina M McManus 20, Kim S Smith 20, Dr Elaine Westwick 20, Dr Stephen W Attwood 23, Dr Frances Bolt 38, 57, Dr Alisha Davies 74, Elen De Lacy 74, Fatima Downing 74, Sue Edwards 74, Lizzie Meadows 75, Sarah Jeremiah 97, Dr Nikki Smith 109 and Luke Foulser 116

Samples and logistics:
