24

25 Abstract

26 Background: Despite effective means to treat SARS-CoV-2 infection, the early  
27 treatment seeking behavior of those newly diagnosed with infection is not clear.

28 Methods: We surveyed users of a national SARS-CoV-2 testing company to assess the  
29 frequency and correlates of early treatment seeking behavior for a positive test result.

30 We recruited adults (18 years or older) who had tested positive for SARS-CoV-2 by  
31 PCR at a large clinical laboratory. To be eligible, individuals had to have a positive test  
32 result within 7 days of enrollment. Surveys were anonymous and voluntary. We  
33 collected data on demographic characteristics, general health care access and  
34 utilization, awareness of treatment for COVID-19, treatment seeking behavior, and  
35 treatments received. Descriptive statistics and odds ratios (OR) with 95% confidence  
36 intervals (95% CI) were calculated on StataSE.

37 Results: Participants were surveyed from 3-7 January 2022: among the 15,991 who  
38 viewed a survey request, 7,647 individuals were eligible and provided responses. The  
39 median age of a respondent was 42 years (interquartile range: 32 to 54), 68.9% of  
40 respondents were women, and respondents represented 33 different states, districts,  
41 and territories. Among respondents, 23.1% reported they had sought treatment or  
42 medical advice for their current COVID-19 diagnosis. Of those who were very aware of  
43 treatment for COVID-19, 31.0% sought treatment versus 16.7% who were unaware ( $p$ -  
44 value < 0.001). The odds of treatment seeking behavior were higher for those that were  
45 contacted by a medical professional after their diagnosis (OR: 4.57 [95% CI: 3.89 to  
46 5.37]), those with a primary doctor (OR: 2.94 [95% CI: 2.52 to 3.43]), those who self-  
47 measured their oxygen saturation (OR: 2.53 [95% CI: 2.25 to 2.84]), and those over 65

48 years of age (OR: 2.36 [95% CI: 2.02 to 2.76]). There was no difference in those  
49 seeking treatment based on heritage, ethnicity, prior COVID-19 diagnosis, state political  
50 affiliation, or vaccination status. The odds of seeking treatment were lower among men  
51 (OR: 0.88 [95% CI: 0.78 to 0.99]) and those without insurance (OR: 0.62 [95% CI: 0.52  
52 to 0.72]). The most common treatment locations were clinics and most common  
53 treatments were Vitamin C, Vitamin D, Zinc, Tylenol, and NSAIDs.  
54 Conclusion: More public outreach is needed to raise awareness of the benefits of  
55 treatment for COVID-19. We found that people who were more aware about treatment  
56 for COVID-19 were more likely to seek medical advice or therapy. Efforts to increase  
57 awareness might increase early treatment for SARS-CoV-2 infection. Increased  
58 outreach with treatment facilitation from medical professionals and/or public health staff  
59 to those with newly detected SARS-CoV-2 infections, particularly among those at  
60 higher-risk of complications, might also be helpful.

61

62 Main Text (586/600)

63 COVID-19 continues to cause severe disease, hospitalization, and death. Despite  
64 effective means to treat SARS-CoV-2 infection,<sup>1-4</sup> the early treatment seeking behavior  
65 of those newly diagnosed with infection is not clear. We surveyed users of a national  
66 SARS-CoV-2 testing company to assess the frequency and correlates of early treatment  
67 seeking behavior for a positive test result.

68

69 We recruited adults (18 years or older) who had tested positive for SARS-CoV-2 by  
70 PCR at a large clinical laboratory (Curative, San Dimas, CA). To be eligible, individuals  
71 had to have a positive test result within 7 days of enrollment. Surveys were anonymous  
72 and voluntary. We collected data on demographic characteristics, general health care  
73 access and utilization, awareness of treatment for COVID-19, treatment seeking  
74 behavior, and treatments received. Descriptive statistics and odds ratios (OR) with 95%  
75 confidence intervals (95% CI) were calculated on StataSE (StataCorp, College Station,  
76 TX). Chi-squared tests and linear regression analysis were used to compare categorical  
77 variables and continuous variables between groups, respectively. Advarra granted the  
78 study IRB exempt (Pro00059961).

79

80 Participants were surveyed from 3-7 January 2022: among the 15,991 who viewed a  
81 survey request, 7,647 individuals were eligible and provided responses. The median  
82 age of a respondent was 42 years (interquartile range: 32 to 54), 68.9% of respondents  
83 were women, and respondents represented 33 different states, districts, and territories.  
84 Among those surveyed, 66.7% identified as White, 30.6% as Hispanic, 12.1% as Black

85 or African American, 6.2% as Asian, and 1.2% as Pacific Islander or Native American.

86 Most respondents reported they were vaccinated (89.3%).

87

88 Among respondents, 23.1% reported they had sought treatment or medical advice for  
89 their current COVID-19 diagnosis (Table 1). Of those who were very aware of treatment  
90 for COVID-19, 31.0% sought treatment versus 16.7% who were unaware (p-value<  
91 0.001). The odds of treatment seeking behavior were higher for those that were  
92 contacted by a medical professional after their diagnosis (OR: 4.57 [95% CI: 3.89 to  
93 5.37]), those with a primary doctor (OR: 2.94 [95% CI: 2.52 to 3.43]), those who self-  
94 measured their oxygen saturation (OR: 2.53 [95% CI: 2.25 to 2.84]), and those over 65  
95 years of age (OR: 2.36 [95% CI: 2.02 to 2.76]).

96

97 There was no difference in those seeking treatment based on heritage, ethnicity, prior  
98 COVID-19 diagnosis, state political affiliation, or vaccination status. The odds of seeking  
99 treatment were lower among men (OR: 0.88 [95% CI: 0.78 to 0.99]) and those without  
100 insurance (OR: 0.62 [95% CI: 0.52 to 0.72]). The most common treatment locations  
101 were clinics and most common treatments were Vitamin C, Vitamin D, Zinc, Tylenol,  
102 and NSAIDs (Table 2).

103

104 Due to the timing of the survey, infection was most likely due to the Omicron variant of  
105 SARS-CoV-2, which might be less severe in those with prior immunity.<sup>5</sup> The most  
106 commonly used treatments were over-the-counter medications for symptom relief. Few  
107 had received therapies known to reduce risk of disease progression.<sup>4,6</sup> There were also

108 continued reports of non-beneficial medication use, i.e., ivermectin and  
109 hydroxychloroquine.

110  
111 More public outreach is needed to raise awareness of the benefits of treatment for  
112 COVID-19. We found that people who were more aware about treatment for COVID-19  
113 were more likely to seek medical advice or therapy. Efforts to increase awareness might  
114 increase early treatment for SARS-CoV-2 infection. Additionally, those who were  
115 contacted by a health professional were more likely to seek treatment or medical advice  
116 for COVID-19. Increased outreach with treatment facilitation from medical professionals  
117 and/or public health staff to those with newly detected SARS-CoV-2 infections,  
118 particularly among those at higher-risk of complications, might also be helpful.
