ABSTRACT

IMPORTANCE: Multimorbidity is common, but the prevalence and outcomes of the specific combinations of co-occurring disease has not been systematically examined in the general U.S. adult population.

OBJECTIVE: To identify and measure the burden of highly prevalent combinations of chronic conditions that are treated among adults 18 and older in the United States.

DESIGN: Cross-sectional analysis of the Medical Expenditure Panel Survey (MEPS), 2016–2019.

SETTING: U.S. households

PARTICIPANTS: Nationally-representative sample of civilian non-institutionalized adults 18 and older (n=89,947).

MEASUREMENTS: Multimorbidity – defined as any combination of 20 different self-reported chronic conditions treated during the study period. Frequent pattern mining and association rule mining were used to identify the most common combinations of multimorbidity that met a threshold of occurring in at least one million subjects of the weighted study population. The main measures and outcomes were annual self-reported prevalence, total medical expenditures, and perceived fair/poor health. Generalized linear regression was used to estimate age-race-sex adjusted odds ratios for perceived health. Taylor series estimation produced weighted estimates and 95% confidence intervals.

RESULTS: An estimated 32.9% of the US population is treated for two or more chronic conditions annually. Frequent pattern mining yielded 259 unique combinations of chronic disease, including 77 two-way (dyad), 134 three-way (triad), 47 four-way, and one five-way combinations that affect one million or more of the weighted study population. An estimated 30.8 million people or 12.4% (95% CI: 12.0-12.7%) of the U.S. adult population is treated for at least {Hypertension & Hyperlipidemia} – the most common two-way combination. The

combination of {Diabetes & Arthritis & Cardiovascular disease} was associated with the highest median annual medical expenditures ($23,850, [Interquartile range: $11,593 – $44,616]), and the combination of {Diabetes & Arthritis & Asthma/COPD} had the highest age-race-sex adjusted odds ratio of fair/poor self-rated health (adjusted odd ratio: 6.9, [95%CI: 5.4 – 8.8]).

CONCLUSION: This study demonstrates the many combinations of disease are highly prevalent in the population. However, most research and clinical practice guidelines are single-disease focused. The combinations reported here could be prioritized for evidence-based research, especially those most associated with poor health and high medical costs.

INTRODUCTION

An estimated 42% percent of American adults suffer from multiple chronic conditions (i.e. multimorbidity).[1] Persons with multimorbidity are at higher mortality rates, lower health-related quality life, increased healthcare use, and are at higher risk for many poor health outcome events including adverse drug events.[2-6] While numerous data exist on the prevalence of single chronic conditions[1,7], much less is known about the prevalence of *specific combinations* of multimorbidity. Most prevalence studies of multimorbidity are based on counts of conditions.[8,9] Studies that have examined the prevalence of specific combinations of multimorbidity in the US have been mostly limited to dyad and triad combinations[10-12] or a small number of conditions,[13,14] or conducted in a specific sub-populations[15] or limited to older adults.[13,16]

The prevalence of specific combinations of multimorbidity of the general community-dwelling adult population has not been established comprehensively in the United States. The US Department of Health and Human Services' strategic framework on multimorbidity identified understanding the epidemiology of constellations of multiple chronic conditions as one of its top research goals.[17] More recently, the Academy of Medical Sciences listed identifying trends and patterns of multimorbidity, and the specific clusters that cause the greatest burden as its top two goals in multimorbidity research.[18] Evidence about which conditions most commonly co-occur together and their impact on outcomes can help inform decisions about how to optimize prevention and treatment strategies, and design health systems to offer more holistic care rather the usual practice of treating one condition at a time.[18] Further, measuring the impact of multimorbidity based on counts of conditions or weighted scores may miss important heterogeneity, because the specific combinations of chronic disease matter in terms of health outcomes[19] including mortality and poor health,[5] ADL/IADL limitations,[14,20] and cost and utilization.[6]

The goal of this study was to identify and rank the most frequent multi-way (two-way, three-way, four-way, etc...) combinations of multimorbidity treated among adults in the United States. Innovative machine learning algorithms – frequent pattern mining and association rule learning – were used to identify all combinations of multimorbidity occurring in one million or more U.S. adults. The association of these combinations with average per capita direct medical expenditures and perceived fair or poor health status was also examined.

METHODS

This study was a cross-sectional analysis of the 2016 – 2019 Medical Expenditure Panel Survey Household Component (MEPS). The MEPS is a large-scale panel survey of a nationally representative sample of households in the United States and is administered by the Agency for Healthcare Research and Quality (AHRQ).[21] The MEPS collects data at the person-level on numerous topics including medical expenditures, utilization, medical conditions, health status, and demographics. Interviews are conducted in-person using computer-assisted personal interview (CAPI) technology.

This study included all adults age 18 and older with non-zero weights. Subjects with missing data on self-reported health or expenditures were excluded (n≤10). The final unweighted sample was 89,947 adults. This study was determined to be Not Human Subjects Research by the author's Institutional Review Board (#NHR-15-48).

Health conditions are self-reported through open-ended questions about conditions reported to be associated with health care events.[22] The respondents verbatim text responses are coded according to the International Classification of Diseases, Tenth Revision, Clinical Modification (ICD-10-CM). Treatment of these conditions may have been received through inpatient stays, outpatient or office-based visits, emergency department visits, home health care, or prescribed medications. Chronic conditions were then classified into one of 20 primary

care relevant chronic conditions used in recent studies of multimorbidity.[23,24] A list of each chronic condition categories and corresponding ICD-10-CM codes is included in the appendix (eTable 1).

Perceived health was assessed by asking respondents to rate their health as excellent (1), very good (2), good (3), fair (4), or poor (5). A response of fair or poor was categorized as "poor perceived health."

Medical expenditures are defined as the sum of direct payments for care provided during the year, including out-of-pocket payments and payments by private insurance, Medicaid, Medicare, and other sources. Expenditure data are collected through both self-report and through data collected from the respondents' physicians, hospitals, and pharmacies, when available. Imputation is used when data are missing or payments are made under capitated plans.[22] Expenditures were adjusted for annual inflation and are reported in terms of 2019 dollars using the Personal Consumption Expenditure Health Price Index from the Bureau of Economic Analysis.[25]

Statistical Analysis and Measures:

Association Rule Mining (ARM) was used to identify the frequent multi-way combinations of chronic disease.[26] ARM is a machine learning method originally developed by computer scientists to find items commonly purchased together in the same transaction (also called market-basket analysis), but has since been extended to other applications, including medicine and bioinformatics (cites; Brin, 1997, other examples).[15,27–29] The method was applied here by treating each subject in the study data as the "transaction," and each chronic condition as the "items" to find the most frequently co-occurring combinations. As there are 1,048,576 (2^{20}) possible combinations of 20 conditions, ARM uses the Apriori algorithm and a minimum prevalence or "support" threshold to trim the search space and make it computationally feasible.

In brief, the Apriori algorithm states that if a given combination is below the minimum support threshold, then all of the supersets (the combination + one or more additional conditions) are also below the threshold. The minimum support is defined by the user; it was set at 0.20% for the initial pass, and then after applying survey weights, any combinations with a point estimate of less than one million adults (~0.40% of the U.S. adult population) was dropped.

The MEPS uses a complex stratified random sampling design. Design-based survey methods (i.e. Taylor series estimation) were used to account for stratification and clustering effects when estimating variances. Survey weights were divided by four to produce all study results in terms of annual values. Person-level weights were applied to get the average annual estimated number and percent of persons with a disease combination and 95% confidence interval. The median and average annual per capita medical expenditures and percent self-reporting fair/poor health status was calculated for each combination after applying weights.

When ranking combinations by expenditures or poor health, a minimum improvement criteria of 10% was set to filter out rules that are redundant or offer little new information on the outcome measure over more parsimonious combinations.[30,31] The age-race-sex adjusted odds ratio of fair/poor health status was estimated for each disease combination using survey weighted generalized linear regression with a logit link function. The adjustment variables were age as a continuous variable with splines, race (Hispanic, non-Hispanic white, non-Hispanic black, non-Hispanic Asian, and other), and sex.

Data pre-processing was performed using SAS version 9.4 for Windows. The analysis was conducted using R version 4.1.0, RStudio (v. 1.4.1717), and R packages: arules (v. 1.6-8) and survey (v. 4.1-1).[32,33]

RESULTS

The total weighted study population was 249.2 million adults age 18 and older, with 82.0 million (32.9%) reporting receiving treatment for two or more conditions (Table 1) in a single year. 51.7 million (20.7%) adults have three or more conditions, and 30.6 million (12.3%) have 4 or more conditions. A dose response increase is evident between number of chronic conditions and the percentage reporting fair/poor perceived health and average annual medical expenditures.

Frequent pattern mining yielded 259 unique combinations of chronic disease, including 77 two-way, 134 three-way, 47 four-way, and one five-way combinations that affect one million or more of the weighted study population. The top 25 of these multi-way combinations, ranked by prevalence are shown in Table 2, and the full table is included in supplement (eTable 2). There are eight combinations that affect 10 million or more adults, 32 combinations that affect 5 million or more adults, and 129 that affect 2 million or more adults per year. There were not any six-way or higher combinations that met the minimum prevalence threshold.

Combinations of conditions and corresponding prevalence estimates represent "at least", rather than "exactly." For example, an estimated 31.5 million people (12.7%, 95%CI: 12.2% – 13.3%) of the U.S. adult population are treated for *at least* hypertension & hyperlipidemia – the most common combination (Table 1). An estimated 19.3 million people (4.8%, 95%CI: 4.5% – 5.2%) have *at least* hypertension & hyperlipidemia & arthritis – the most common 3-way combination, and fifth most common combination overall. These 12.0 million are a subset of the 31.5 million with at least hypertension & hyperlipidemia.

The combination {Diabetes & Urinary problems & Cardiovascular disease} had the highest average annual medical expenditures per capita ($35,782, 95%CI: $31,129 – $40,435) among combinations of disease affecting one million or more adults (Table 3). This was 2.1 times higher than the average for having any three or more chronic conditions ($16,819), and was also at least 23.1% higher than the average expenditures for any single or two-way

combinations of those three disease alone. Average expenditures were higher than median expenditures across the board, indicating the right-skewed nature of expenditures. The combination of {Diabetes & Arthritis & Cardiovascular disease} had the highest median annual expenditures per capita ($23,850, Interquartile range: $11,593 – $44,616).

The combination of {Diabetes & Asthma/COPD & Cardiovascular disease} was also most associated with perceived poor health status with an adjusted odds ratio of 6.9 (5.4 – 8.8) (Table 3). The 62.9% reporting fair/poor health was at least 12.6% higher than any single or two-way combination of those three diseases, and was 2.1 times higher than the average percent reporting fair/poor health among those with any three or more chronic conditions.

DISCUSSION

This study combined data mining with survey epidemiology to comprehensively identify and estimate the treatment prevalence of the most frequent combinations of multimorbidity in the United States. This analysis showed that certain multimorbidity combinations of disease are quite common in the US, occurring in one million or more adults. Despite this, most evidence-based practice guidelines are single-disease focused, and few, if any, clinical trials have been conducted on the optimal care management for most of these multimorbidity combinations.[6] The highly prevalent combinations reported here could be prioritized for future observational and intervention studies.

This study has several strengths. First, it represents the most comprehensive attempt to identify the prevalence of multimorbidity combinations in the general adult population in the United States. A nationally representative sample was used to identify the combinations and estimate the prevalence using survey-weighted techniques. The MEPS database is also unique in its condition enumeration approach, which allows for a more comprehensive capture of different chronic conditions. While most national surveys only ask questions on a fixed number

of diseases, the MEPS uses open-ended responses and reconciliation between utilization records. Administrative sources like claims data would also be able to capture a comprehensive set of conditions, but these would be limited to patients for a given payer and would not capture the uninsured. Electronic health records are typically limited to a single health care system, and are not nationally-representative. Association rule mining allows for the identification of highly prevalent combinations in a quick and computationally efficient manner, while filtering out combinations that are sparse. While this study focuses on highly prevalent combinations occurring in over 1 million adults, the method could be used to identify higher order combinations by setting a lower prevalence thresholds.

This study also has several limitations. The MEPS provides accurate estimates of treated prevalence for chronic disease, but this is likely lower than the underlying population prevalence for some conditions.[22] On the other hand, the focus on treated conditions represent those for which care decisions between multiple conditions may conflict. The MEPS includes community-dwelling subjects only, meaning institutionalized persons such as nursing home and assisted living residents are excluded. Estimates of total expenditures are typically lower than what is estimated from the National Health Expenditure Accounts (NHEA), because the MEPS does not include these institutionalized populations.[34] ICD-10 codes were classified into 20 primary-care relevant conditions using an established algorithm, but other classification systems may result in different combinations and prevalence estimates.

CONCLUSION

This cross-sectional analysis of a nationally-representative survey showed that certain multimorbidity combinations of disease are quite common in the US, occurring in one million or more adults. The combinations reported here could be prioritized for evidence-based research and integration into practice guidelines, especially those most associated with poor health and high medical costs.

Non-Hispanic Asian only	3,355	15,133,000	62.4%	37.6%	20.0%	11.3%	5.4%
Other or Multiple Race	1,359	7,481,000	47.8%	52.2%	32.7%	21.0%	12.8%
Self-rated Fair/Poor Health	7,201	31,085,000	19.0%	81.0%	64.6%	48.8%	34.3%
Per capita medical expenditures in 2019 dollars (Median, IQR)	---	---	$322 ($0 – $1,382)	$4,176 ($1,523 – $11,067)	$6,208 ($2,558 – $14,858)	$8,177 ($3,610 – $18,756)	$10,821 ($5,045 – $23,712)

Table 1 caption: Survey-weighted estimates from pooling the 2016-2019 Medical Expenditure Panel Survey. Weighted estimates have been annualized by taking the average over the four year study period. Row percentages are reported under each count of conditions column.

Table 2: **Combinations of Multimorbidity among U.S. Adults, Ranked by Treated Prevalence, 2016 – 2019**

Rank	Combination of Chronic Disease	No. of cond-itions	No. in unweighted sample	Weighted No. of Adults (in millions)	Prevalence, % (95% CI)	Observed to Expected Ratio (95% CI)
1	Hypertension & Hyperlipidemia	2	11,967	30.80	12.4 (12.0 - 12.8)	2.7 (2.6 - 2.7)
2	Hypertension & Diabetes	2	6,980	16.54	6.6 (6.4 - 6.9)	2.6 (2.5 - 2.7)
3	Hypertension & Musculoskeletal condition	2	5,681	14.53	5.8 (5.6 - 6.1)	1.6 (1.6 - 1.7)
4	Hyperlipidemia & Diabetes	2	5,911	14.28	5.7 (5.5 - 6.0)	3.1 (3.0 - 3.2)
5	Hypertension & Hyperlipidemia & Diabetes	3	4,821	11.51	4.6 (4.4 - 4.9)	9.5 (9.3 - 9.8)
6	Hyperlipidemia & Musculoskeletal condition	2	4,315	11.28	4.5 (4.3 - 4.7)	1.7 (1.6 - 1.8)
7	Hypertension & Arthritis	2	4,390	10.70	4.3 (4.1 - 4.5)	2.3 (2.3 - 2.4)
8	Hypertension & Stomach problems	2	4,004	10.01	4.0 (3.8 - 4.3)	2.3 (2.2 - 2.4)
9	Hypertension & Cardiovascular disease	2	3,815	9.81	3.9 (3.7 - 4.1)	2.7 (2.6 - 2.8)
10	Hypertension & Urinary problems	2	3,552	9.11	3.7 (3.5 - 3.8)	2.0 (2.0 - 2.1)
11	Hypertension & Asthma/COPD	2	3,494	8.83	3.5 (3.3 - 3.8)	1.8 (1.7 - 1.8)
12	Hypertension & Thyroid disorder	2	3,309	8.79	3.5 (3.3 - 3.7)	1.8 (1.7 - 1.8)
13	Hyperlipidemia & Cardiovascular disease	2	3,235	8.54	3.4 (3.2 - 3.6)	3.2 (3.1 - 3.3)
14	Hyperlipidemia & Arthritis	2	3,371	8.43	3.4 (3.2 - 3.6)	2.5 (2.4 - 2.6)
15	Hyperlipidemia & Stomach problems	2	3,199	8.08	3.2 (3.0 - 3.4)	2.5 (2.4 - 2.6)
16	Hypertension & Depression/Anxiety	2	3,010	7.89	3.2 (3.0 - 3.4)	1.5 (1.4 - 1.6)
17	Hypertension & Hyperlipidemia & Musculoskeletal condition	3	3,103	7.87	3.2 (3.0 - 3.3)	4.7 (4.5 - 4.8)
18	Musculoskeletal condition & Arthritis	2	2,916	7.53	3.0 (2.9 - 3.2)	2.7 (2.6 - 2.9)
19	Hyperlipidemia & Thyroid disorder	2	2,753	7.42	3.0 (2.8 - 3.2)	2.0 (2.0 - 2.1)
20	Hyperlipidemia & Urinary problems	2	2,827	7.34	2.9 (2.8 - 3.1)	2.2 (2.1 - 2.3)
21	Hypertension & Hyperlipidemia & Cardiovascular disease	3	2,651	6.82	2.7 (2.6 - 2.9)	10.0 (9.6 - 10.4)
22	Hyperlipidemia & Asthma/COPD	2	2,588	6.68	2.7 (2.5 - 2.8)	1.8 (1.7 - 1.9)
23	Hypertension & Hyperlipidemia & Arthritis	3	2,659	6.45	2.6 (2.4 - 2.8)	7.5 (7.2 - 7.8)

24	Musculoskeletal condition & Depression/Anxiety	2	2,333	6.37	2.6 (2.4 - 2.7)	2.0 (1.9 - 2.1)
25	Hypertension & Cancer	2	2,150	6.09	2.4 (2.3 - 2.6)	2.0 (1.9 - 2.1)

Table 2 Caption: Top 25 multi-way combinations of chronic disease ranked by prevalence from the 2016-2019 Medical Expenditure Panel Survey (MEPS). Weighted number and percent and 95% confidence intervals were calculated by applying population weights using Taylor-series methods (i.e. complex survey methods) to account for the complex sampling design of the MEPS. Weighted estimates have been annualized by taking the average over the four-year study period. The observed to expected ratio (also known as lift) is the observed prevalence of the combination divided by the expected prevalence of the combination if each disease within the combination were statistically independent.

Table 3: Frequent Combinations of Multimorbidity among U.S. Adults, Ranked by Average Medical Expenditures, 2016 – 2019

Rank	Combination of Chronic Conditions	No. of conditions	Weighted No. of Adults (in millions)	No. in unweighted sample	Mean Annual Medical Expenditures (95% CI)	Percent Increase Over Highest Superset	Median Annual Medical Expenditures
1	Diabetes & Urinary problems & Cardiovascular disease	3	1.13	477	$35,782 ($31,129 - $40,435)	23.1	$21,608
2	Diabetes & Heart Failure	2	1.02	410	$35,125 ($29,813 - $40,437)	36.1	$18,950
3	Hypertension & Cardiovascular disease & Heart Failure	3	1.15	427	$33,882 ($29,210 - $38,554)	1.3	$18,743
4	Diabetes & Arthritis & Cardiovascular disease	3	1.06	446	$33,856 ($30,005 - $37,707)	16.4	$23,850
5	Diabetes & Stomach problems & Cardiovascular disease	3	1.05	444	$33,823 ($29,942 - $37,704)	16.3	$22,992
6	Cardiovascular disease & Heart Failure	2	1.42	526	$33,451 ($29,034 - $37,868)	29.6	$18,720
7	Hypertension & Musculoskeletal condition & Diabetes & Urinary problems	4	1.04	439	$33,207 ($28,614 - $37,801)	4.7	$23,058
8	Musculoskeletal condition & Diabetes & Cardiovascular disease	3	1.24	508	$32,345 ($28,190 - $36,499)	11.2	$20,053
9	Musculoskeletal condition & Diabetes & Urinary problems	3	1.34	559	$31,711 ($27,927 - $35,494)	22.4	$21,787
10	Diabetes & Asthma/COPD & Stomach problems	3	1.08	469	$31,674 ($28,038 - $35,309)	25.4	$21,295
11	Hypertension & Hyperlipidemia & Heart Failure	3	1.45	539	$31,532 ($27,782 - $35,282)	7.3	$16,634
12	Musculoskeletal condition & Stomach problems & Cardiovascular disease	3	1.16	460	$31,175 ($27,542 - $34,809)	12.5	$18,853
13	Musculoskeletal condition & Urinary problems & Cardiovascular disease	3	1.03	398	$31,017 ($26,496 - $35,538)	14.1	$19,821
14	Hypertension & Hyperlipidemia & Diabetes & Cancer	4	1.19	447	$30,820 ($25,151 - $36,488)	1.6	$14,546
15	Hyperlipidemia & Cardiovascular disease & Cancer	3	1.36	492	$30,496 ($26,375 - $34,617)	3.1	$17,045

16	Hyperlipidemia & Diabetes & Cancer	3	1.37	522	$30,345 ($24,525 - $36,164)	11.5	$14,604
17	Hypertension & Hyperlipidemia & Cardiovascular disease & Cancer	4	1.09	393	$29,972 ($25,722 - $34,221)	-1.7	$17,395
18	Hypertension & Hyperlipidemia & Asthma/COPD & Cardiovascular disease	4	1.50	591	$29,915 ($26,359 - $33,471)	3.3	$19,539
19	Hypertension & Hyperlipidemia & Diabetes & Cardiovascular disease	4	2.77	1,156	$29,885 ($26,978 - $32,792)	2.0	$16,486
20	Hyperlipidemia & Musculoskeletal condition & Diabetes & Stomach problems	4	1.04	453	$29,786 ($26,293 - $33,278)	6.5	$18,266
21	Hypertension & Diabetes & Arthritis & Stomach problems	4	1.03	453	$29,681 ($25,468 - $33,894)	1.7	$17,309
22	Cardiovascular disease & Cancer	2	2.14	784	$29,582 ($26,317 - $32,848)	33.1	$16,646
23	Hypertension & Hyperlipidemia & Urinary problems & Cardiovascular disease	4	1.70	644	$29,551 ($26,204 - $32,899)	3.6	$17,866
24	Diabetes & Stroke	2	1.13	472	$29,457 ($25,015 - $33,898)	24.8	$17,621
25	Hyperlipidemia & Heart Failure	2	1.75	657	$29,392 ($26,183 - $32,601)	13.9	$15,905

Table 3 Caption: Top 25 multi-way combinations of chronic disease ranked by average medical expenditures from the 2016-2019 Medical Expenditure Panel Survey (MEPS). Weighted means and 95% confidence intervals were calculated by applying population weights using Taylor-series methods (i.e. complex survey methods) to account for the complex sampling design of the MEPS. Weighted estimates have been annualized by taking the average over the four-year study period. Percent Increase Over Highest Superset represents the percentage increase in cost per capita that that disease combination has over any simpler combination.

Table 4: Association of Frequent Combinations of Multimorbidity with Perceived Fair or Poor Health Status, 2016 – 2019

Rank	Combination of Chronic Disease	No. of cond-itions	Weighted No. of Adults (in millions)	No. in unweighted sample	Percent reporting fair or poor health	Percent increase over highest superset	Unadjusted Odds Ratio (95% CI)	Adjusted Odds Ratio (95% CI)
1	Diabetes & Asthma/COPD & Arthritis	3	1.18	321	62.9	12.6	10.1 (8.1 - 12.7)	6.9 (5.4 - 8.8)
2	Musculoskelatal & Diabetes & Asthma/COPD	3	1.36	362	63.2	12.9	9.5 (7.8 - 11.6)	6.6 (5.4 - 8.1)
3	Musculoskelatal & Diabetes & Depression/Anxiety	3	1.08	282	61.0	13.6	8.3 (6.5 - 10.7)	6.2 (4.7 - 8.0)
4	Diabetes & Asthma/COPD & Stomach problems	3	1.08	293	62.5	11.9	8.9 (7.1 - 11.1)	6.2 (4.9 - 7.8)
5	Depression/Anxiety & Asthma/COPD & Arthritis	3	1.00	255	60.4	17.4	8.1 (6.3 - 10.4)	6.1 (4.7 - 7.9)
6	Musculoskelatal & Depression/Anxiety & Asthma/COPD	3	1.56	369	58.4	14.5	7.4 (5.9 - 9.2)	6.0 (4.8 - 7.6)
7	Depression/Anxiety & Asthma/COPD & Stomach problems	3	1.04	253	59.0	15.3	7.4 (5.7 - 9.5)	5.9 (4.6 - 7.7)
8	Diabetes & Heart Failure	2	1.02	237	57.8	25.6	8.4 (6.4 - 11.1)	5.6 (4.2 - 7.4)
9	Hyperlipidemia & Depression/Anxiety & Asthma/COPD	3	1.39	323	57.6	13.3	7.5 (6.0 - 9.5)	5.5 (4.3 - 7.0)
10	Diabetes & Asthma/COPD	2	3.66	838	55.0	34.9	7.4 (6.5 - 8.5)	5.3 (4.6 - 6.1)
11	Musculoskelatal & Diabetes & Arthritis	3	1.79	431	57.2	13.9	7.8 (6.4 - 9.4)	5.3 (4.4 - 6.5)
12	Diabetes & Arthritis & Cardiovascular disease	3	1.06	260	58.3	15.5	8.1 (6.2 - 10.7)	5.2 (3.9 - 6.9)
13	Hypertension & Depression/Anxiety & Asthma/COPD	3	1.79	413	56.8	12.1	7.0 (5.7 - 8.6)	5.2 (4.2 - 6.4)
14	Diabetes & Stroke	2	1.13	260	55.1	15.5	7.9 (6.4 - 9.8)	5.2 (4.1 - 6.5)
15	Musculoskelatal & Asthma/COPD & Arthritis	3	1.87	418	55.2	10.9	7.0 (5.9 - 8.5)	5.1 (4.2 - 6.1)
16	Diabetes & Urinary problems & Cardiovascular disease	3	1.13	271	56.8	14.9	7.8 (6.0 - 10.1)	5.0 (3.9 - 6.6)
17	Diabetes & Arthritis & Stomach problems	3	1.24	303	56.6	13.0	7.5 (6.0 - 9.4)	5.0 (4.0 - 6.3)
18	Asthma/COPD & Cardiovascular disease	2	2.93	603	53.7	30.3	7.5 (6.4 - 8.8)	5.0 (4.3 - 5.8)
19	Diabetes & Stomach problems & Cardiovascular disease	3	1.05	250	56.3	14.1	7.5 (6.0 - 9.5)	5.0 (3.9 - 6.3)
20	Diabetes & Depression/Anxiety	2	3.04	639	52.7	32.1	6.4 (5.6 - 7.5)	4.9 (4.2 - 5.7)
21	Musculoskelatal & Diabetes & Stomach	3	1.47	353	56.1	15.0	7.1 (5.9 - 8.6)	4.9 (4.0 - 5.9)

	problems							
22	Musculoskelatal & Diabetes & Urinary problems	3	1.34	307	54.9	13.1	7.3 (5.9 - 9.1)	4.9 (3.9 - 6.1)
23	Cardiovascular disease & Stroke	2	1.10	239	53.8	13.5	7.8 (6.1 - 9.9)	4.9 (3.8 - 6.2)
24	Diabetes & Arthritis & Urinary problems	3	1.08	254	55.2	10.8	7.5 (5.9 - 9.4)	4.8 (3.8 - 6.2)
25	Depression/Anxiety & Asthma/COPD	2	3.88	730	49.9	30.7	5.4 (4.7 - 6.3)	4.8 (4.2 - 5.6)

Table 4 Caption: Top 25 multi-way combinations of chronic disease ranked by highest percent of population self-reporting fair or poor health from the 2016-2019 Medical Expenditure Panel Survey (MEPS). Weighted percent, odds ratio, adjusted odds ratios, and 95% confidence intervals were calculated by applying population weights using Taylor-series methods (i.e. complex survey methods) to account for the complex sampling design of the MEPS. Weighted estimates have been annualized by taking the average over the four-year study period. Percent Increase Over Highest Superset represents the percentage increase in cost per capita that that disease combination has over any simpler combination. Adjusted odds ratios were calculated using log-binomial models adjusting for age, race, and sex, and Taylor-series methods for standard errors.
