44

45 **ABSTRACT**

46 **Objectives**

47 To describe the severity of maternal infection when the Omicron SARS-CoV-2 variant was
48 dominant (15/12/21-14/01/22) and compare outcomes among groups with different
49 vaccination status.

50 **Design:** Prospective cohort study

51 **Setting:** UK consultant-led maternity units

52 **Participants:** Pregnant women hospitalised with a positive SARS-CoV-2 PCR test up to 7
53 days prior to admission and/or during admission up to 2 days after giving birth.

54 **Main outcome measures:** Symptomatic or asymptomatic infection. Vaccination status.
55 Severity of maternal infection (moderate or severe infection according to modified WHO
56 criteria). Mode of birth and perinatal outcomes.

57 **Results:** Out of 1561 women admitted to hospital with SARS-CoV-2 infection, 449 (28.8%)
58 were symptomatic. Among symptomatic women admitted, 86 (19.2%) had moderate to
59 severe infection; 51 (11.4%) had pneumonia on imaging, 62 (14.3%) received respiratory
60 support, and 19 (4.2%) were admitted to the intensive care unit (ICU). Three women died
61 (0.7%). Vaccination status was known for 383 symptomatic women (85.3%) women; 249
62 (65.0%) were unvaccinated, 45 (11.7%) had received one vaccine dose, 76 (19.8%) had
63 received two doses and 13 (3.4%) had received three doses. 59/249 (23.7%) unvaccinated
64 women had moderate to severe infection, compared to 10/45 (22.2%) who had one dose,
65 9/76 (11.8%) who had two doses and 0/13 (0%) who had three doses. Among the 19
66 symptomatic women admitted to ICU, 14 (73.7%) were unvaccinated, 3 (15.8%) had
67 received one dose, 1 (5.3%) had received two doses, 0 (0%) had received 3 doses and 1
68 (5.3%) had unknown vaccination status.

69 **Conclusion**

70 The risk of severe respiratory disease amongst unvaccinated pregnant women admitted with
71 symptomatic SARS-CoV-2 infection during the Omicron dominance period was comparable
72 to that observed during the period the wildtype variant was dominant. Most women with
73 severe disease were unvaccinated. Vaccine coverage among pregnant women admitted
74 with SARS-CoV-2 was low compared to the overall pregnancy population and very low
75 compared to the general population. Ongoing action to prioritise and advocate for vaccine
76 uptake in pregnancy is essential.

SUMMARY BOX

What is already known on this topic

- In non-pregnant adults, growing evidence indicates a lower risk of severe respiratory disease with the Omicron SARS-CoV-2 Variant of Concern (VOC) .
- Pregnant women admitted during the periods in which the Alpha and Delta VOC were dominant were at increased risk of moderate to severe SARS-CoV-2 infection compared to the period when the original wildtype infection was dominant.
- Most women admitted to hospital with symptomatic SARS-CoV-2 infection have been unvaccinated.

What this study adds

- One in four women who had received no vaccine or a single dose had moderate to severe infection, compared with one in eight women who had received two doses and no women who had received three doses
- The proportional rate of moderate to severe infection in unvaccinated pregnant women during the Omicron dominance period is similar to the rate observed during the wildtype dominance period
- One in eight symptomatic admitted pregnant women needed respiratory support during the period when Omicron was dominant

78 **INTRODUCTION**

79 In 2020 the World Health Organization's (WHO) living systematic review concluded that
80 SARS-CoV-2 infection during pregnancy was associated with an increased risk of admission
81 to intensive care (ICU) for the mother, increased risk of preterm birth and admission for
82 neonatal care for the infant.¹ Included studies initially contained data predominately from the
83 USA and China, with few active population-based surveillance studies. The last update was
84 published in April 2021 and consequently included studies comprise mainly the Variants of
85 Concern (VOC) prior to Delta.

86

87 In the UK, a new SARS-CoV-2 VOC (B.1.1.529, Omicron) was initially reported in November
88 2021 and dominated by mid-December 2021.² With the Alpha (B.1.1.7) and Delta (B.1.617)
89 VOC, severe maternal infection was more frequent compared to the wildtype period, and
90 perinatal outcomes were worse³⁻⁵. The majority of severe maternal and perinatal outcomes
91 occurred among unvaccinated women during periods with alpha and delta as dominant
92 variants.^{6 7 8} Initial studies of Omicron infection in non-pregnant populations indicate a lower
93 risk of severe pulmonary disease with this variant compared to the previous delta VOC.⁹⁻¹¹

94

95 To date we have not identified any peer-reviewed published studies exploring the impact of
96 infection with the Omicron SARS-CoV-2 variant on pregnant women and perinatal outcomes.
97 There is an urgent need for robust national data to inform women who are pregnant or plan a
98 pregnancy, as well as health professionals providing care for pregnant women, and policy
99 makers. The primary aim of this study was therefore to describe the characteristics of
100 pregnant women admitted to hospital with SARS-CoV-2 infection including vaccination
101 status, severity of infection, pharmacologic management, pregnancy, and perinatal
102 outcomes, in the first period when the Omicron VOC was dominant in the UK.

103

104 **METHODS**

105

106 **Design, data sources and study period**

107 A national, prospective observational cohort study was conducted using the UK Obstetric
108 Surveillance System (UKOSS).¹² This system entails active surveillance with reporting from
109 all 194 hospitals in the UK with a consultant-led maternity unit, and includes well established
110 routines to secure complete reporting.¹³ Information on women who died, or who had
111 stillbirths or neonatal deaths, was cross-checked with data from the organisation responsible
112 for maternal and perinatal death surveillance in the UK (MBRRACE-UK).¹⁴ As individual-
113 level SARS-CoV-2 variant data were not recorded in medical records, the data collection
114 time period was restricted to the period in which the Omicron SARS-CoV-2 variant was the

115 dominant circulating strain in the UK. The cut-off at December 15 was chosen since the
116 variant then represented 50% or more of sequenced new cases from Public Health
117 England.¹¹

118

119 **Study population and study groups**

120 Women were included if they were admitted to hospital during pregnancy and had a positive
121 SARS-CoV-2 PCR test at the time of admission. Hospital admission was defined as an
122 overnight or longer hospital admission for any cause, or admission of any duration to give
123 birth. Women not meeting this case definition were excluded (Figure 1). The included
124 women were categorised in two mutually exclusive groups based on covid-19 symptoms.

125 Symptomatic group: women who were admitted due to covid-19 or who were reported to be
126 symptomatic or who received respiratory support of any kind.

127 Asymptomatic group: women admitted for labour, obstetric care or other reasons and who
128 were not reported to have SARS-CoV-2-related symptoms and who did not receive
129 respiratory support, or who were reported to be asymptomatic if the reason for admission
130 was not known.

131 Vaccination status was categorised as follows; unvaccinated, one dose, two doses and three
132 doses, or vaccination status unknown.

133

134 **Measures**

135 A composite measure indicating moderate to severe SARS-CoV-2 infection was based on
136 the WHO criteria of covid-19 disease severity.¹⁵ Women were classified as having moderate
137 to severe respiratory disease if one or more of the following was reported: oxygen saturation
138 <95% on admission, need for respiratory support, evidence of pneumonia on imaging,
139 admission to ICU, or maternal death. Respiratory support was recorded as the maximum
140 level of support in one of the following categories: oxygen therapy (supplementation on nasal
141 prongs or non-rebreathe mask <15 l/min), high-flow nasal cannula ≥15 l/min or continuous
142 positive airway pressure (CPAP), mechanical ventilation (MV) or extracorporeal membrane
143 oxygenation (ECMO). Mode of birth was categorised as follows; caesarean section prior to
144 or in labour, assisted vaginal birth, unassisted vaginal birth. Gestational age was categorised
145 by completed weeks as <22 weeks, 22 to 27 weeks, 28 to 33 weeks, 34 to 36 weeks and
146 ≥37 weeks for gestational age at admission and gestational age at childbirth. The following
147 perinatal outcomes were included: total births, live births, stillbirths, neonatal unit (NNU)
148 admission, early neonatal death.

149 The following sociodemographic and medical risk factors were included: maternal age, body
150 mass index (BMI) in kg/m², occupation (woman or partner in paid work vs neither in paid
151 work), minority ethnic background (Asian, Black, Chinese, other or mixed ethnic minorities vs

152 White), smoking (current smoker vs non-smoker), medical conditions prior to or during
153 pregnancy (asthma, hypertension, cardiac disease, and diabetes prior to or in pregnancy),
154 parity (nulliparous vs multiparous), plurality (singleton vs multiple).

155

156 Descriptions of pharmacological therapies were based on national guidance on
157 pharmacological therapy issued on 01/07/2020 using the current edition at the time of
158 admission¹⁶.

159

160 **Study registration**

161 The study was registered with ISRCTN, number 40092247 and the protocol is available at
162 <https://www.npeu.ox.ac.uk/ukoss/current-surveillance/covid-19-in-pregnancy>.

163

164 **Role of the funding source**

165 The funder played no role in study design; in the collection, analysis, and interpretation of
166 data; in the writing of the report; or in the decision to submit the paper for publication.

167

168 **Ethics and consent**

169 This study was approved by the HRA NRES Committee East Midlands – Nottingham 1
170 (Ref. Number: 12/EM/0365).

171

172 **Patient and Public Involvement**

173 Patients and public were part of the UKOSS steering committee and involved in study
174 oversight but not in the design, reporting, conduct or dissemination of this study.

175

176 **Statistical methods and analysis**

177 Continuous variables were summarised by medians with interquartile range (IQR) for non-
178 normal distributions. Numbers and proportions are presented, and where data were missing,
179 proportions are presented out of cases known. Statistical analyses were performed using
180 STATA version 17 (Statacorp, TX, USA).

181

182 In this national observational study, the study sample size was governed by the disease
183 incidence, thus no formal power calculation was carried out.

184

185

186

187

188

189 **RESULTS**

190 Of the 1561 women admitted with confirmed SARS-CoV-2 infection between 15th December
191 2021 and 14th January 2022 (Figure 1), 449 (28.8%) were symptomatic and 1112 (71.2%)
192 were asymptomatic.

193

194 The characteristics of included women stratified by admission group are shown in Table 1.
195 The proportion of women aged 35 years or over was similar among symptomatic and
196 asymptomatic women: 27.5% (n=115) and 26.3% (n=278), respectively. BMI of 30kg/m² or
197 more was reported for 29.7% (n=127) and 27.1% (n=289) among symptomatic and
198 asymptomatic women, respectively. Black, Asian or other minority background was reported
199 for 33.5% (n=147) and 38.4% (n=412). In the symptomatic group, 50.8% (n=224) had a
200 gestational age at admission from 22 to 36 completed weeks; this proportion was 22.8%
201 (n=227) in the asymptomatic group. Vaccination status was known for 1274 women (81.6%),
202 383 in the symptomatic group and 891 in the asymptomatic group.

203

204 **Respiratory support and medical treatment for symptomatic women**

205 Two women (0.2%) in the asymptomatic group were admitted to ICU for indications
206 unrelated to their SARS-CoV-2 infection. Overall, 86 (19.2%) of the symptomatic women had
207 at least one indicator of moderate to severe infection (Table 2). However, the proportion of
208 symptomatic women who received any specific pharmacological therapy was low (n=31,
209 6.9%); 0.4% (n=2) received antivirals, 1.6% (n=7) received tocilizumab, 5.8% (n=26)
210 received corticosteroids for maternal indication, and 0.9% (n=4) received monoclonal
211 antibodies. Four women were recruited to the RECOVERY trial. Among the 19 symptomatic
212 women admitted to ICU, 10 (52.6%) received a specific pharmacological therapy, 1 woman
213 (5.3%) received antivirals, 4 (21.0%) received tocilizumab, 9 (47.4%) received
214 corticosteroids for a maternal indication and 2 (10.5%) received monoclonal antibodies.

215

216 **Vaccination status**

217 The proportion of symptomatic women who had received none, one, two or three vaccine
218 doses was 65.1% (n=249), 11.8% (n=45), 19.8% (n=76), and 3.4% (n=13), respectively
219 (Table 1). A total of 78 (20.4%) symptomatic women whose vaccination status was known
220 had a composite measure of moderate to severe infection. More than a fifth of unvaccinated
221 women (59/249, 23.7%) and women who had received one dose (10/45, 22.2%) had
222 moderate to severe infection, compared to one in ten (9/76, 11.8%) who had two doses and
223 none (0/13, 0%) who had three doses. Forty of the women in the two-dose group (52.6%)
224 were known to have received their second vaccine dose more than three months prior to

225 admission; this included five of the nine women who had a composite indicator of moderate
226 to severe infection and the woman who was admitted to ICU. Overall, none of the women
227 (0/68) who had a composite indicator of moderate to severe infection and known vaccination
228 status had completed the vaccination schedule advised to protect the general adult
229 population against severe omicron infection.

230

231 **Pregnancy outcomes**

232 One thousand, one hundred and seventy-two women had completed their pregnancies, 240
233 (53.5%) of the women in the symptomatic group and 932 (83.8%) in the asymptomatic group
234 (Table 4). Almost a third of symptomatic women (n=144, 32.1%) were known to have been
235 discharged still pregnant. The proportion of births at gestational weeks 22 to 36 was 17.8%
236 (n=42) amongst symptomatic women versus 10.7% (n=96) in asymptomatic women. Birth
237 expedited due to covid-19 was reported for 7.6% (n=18) in the symptomatic group; none of
238 these women were known to have received three vaccine doses (Table 5).

239

240 Among 1159 infants, 10 stillbirths were reported; in the symptomatic and asymptomatic
241 groups stillbirths occurred in 0.8% (n=2) and 0.9% (n=8) of total births, respectively (Table
242 6). Eight of the ten stillbirths occurred to women who were unvaccinated or had one vaccine
243 dose, but the role of SARS-CoV-2 in the stillbirth needs to be assessed in formal audit.
244 Admission to a neonatal unit was reported for 15.4% (n=37) of infants born to symptomatic
245 women and 8.5% (n=78) of infants born to asymptomatic women.

246

247 **DISCUSSION**

248 ***Principal findings***

249 This national prospective cohort study has identified that among pregnant women admitted
250 with SARS-CoV-2 infection during the period when the Omicron VOC was dominant around
251 one in four were symptomatic. One in seven of these symptomatic pregnant women needed
252 respiratory support. One in four symptomatic pregnant women who had received no vaccine
253 or a single dose had moderate to severe infection. One in eight symptomatic pregnant
254 women who had received two doses had moderate to severe infection. No symptomatic
255 pregnant women who had received three doses had moderate or severe infection, though
256 the number of pregnant women admitted with symptomatic SARS-CoV-2 infection who had
257 received three vaccine doses was very small. No women with moderate to severe
258 respiratory disease, ICU admission or who died had received vaccines according to the
259 recommended schedule for the general adult population for the Omicron variant.

260

261

262

263 ***Strengths and weaknesses of the study***

264 To our knowledge, this is the first national prospective cohort study to describe pregnancy
265 and perinatal outcomes during the period when the Omicron SARS-CoV-2 variant was
266 dominant. A key strength of these data is the existing mechanism for national case
267 identification of all women admitted to hospital across the UK, and therefore the low risk of
268 selection bias. In the UK, universal SARS-CoV-2 testing for all obstetric admissions was
269 implemented from May 2020. Asymptomatic pregnant women in whom SARS-CoV-2
270 infection is detected by screening on admission, are most commonly admitted to give birth.¹⁷
271 We therefore categorised the included women by cause of admission or symptoms to avoid
272 misclassification bias and increased adverse outcomes being incorrectly attributed to SARS-
273 CoV-2.¹⁸

274

275 Some of the pregnant women who had received two vaccine doses or fewer may also have
276 delayed the second dose due to covid-19 infection; information about previous infection was
277 not available in the current study. These women could potentially be misclassified into a
278 category with lower expected protection while having reduced risk due to post-infection
279 immunity, and this could result in overestimation of the protective effect of different vaccine
280 doses. As with previous analyses,⁵ variant sequencing data were not available for individual
281 women, and a proxy time period was used instead which may be considered a limitation.
282 Additionally, more women in the symptomatic group have not completed their pregnancies,
283 compared to the asymptomatic group, which is likely to affect the observed rates of key
284 neonatal outcomes.

285

286 ***Interpretation and comparison with related studies***

287 The proportion of symptomatic women with moderate to severe infection was lower overall
288 than in the wildtype, Alpha and Delta variant periods in the UK^{5 13}. However, a greater
289 proportion of symptomatic pregnant women had received one or more vaccine doses than in
290 previous variant periods and this needs to be taken into account when comparing outcomes
291 across variant periods, recognising that prior vaccination is likely to confer some degree of
292 protection from both severe illness and symptomatic infection. When solely unvaccinated
293 pregnant women admitted with symptomatic infection are considered, maternal outcomes
294 are very similar to those observed during the initial wildtype infection period⁵. Among those
295 in need of respiratory support, irrespective of vaccination status, the use of mechanic
296 ventilation or ECMO was 16.1% (10/62) and thus lower than previous periods (23.5% in
297 Alpha and 21.4% in Delta periods)⁵.

298

299 Covid-19-specific pharmacological therapies, which are now standard care for non-pregnant
300 patients, were used infrequently, even for women that needed respiratory support. The
301 proportion that received any pharmacological treatment for covid-19 (one or more of an
302 antiviral, tocilizumab, maternal corticosteroids and monoclonal antibodies) was lower than in
303 the Alpha and Delta periods, 6.9% vs 14.9% and 13.6% respectively. While this may partly
304 reflect a lower severity of illness, it is concerning that only around half of pregnant women
305 admitted to ICU due to covid-19 received any covid-19 specific pharmacological treatment.
306 The RCOG recommended in June 2020 that corticosteroid therapy should be considered for
307 all women who were clinically deteriorating due to covid-19.¹⁶ Maternal corticosteroid
308 treatment was reported for 5.8% of symptomatic women during the Omicron period,
309 compared to 12.7% and 12.0% during the Alpha and Delta periods, respectively. In the
310 current study 47% of women admitted to intensive care received corticosteroids.
311 Understanding this persisting low use of evidence-based therapies amongst severely ill
312 pregnant and postpartum women is an increasingly urgent priority.

313

314 Few pregnant women who had received two or more doses of vaccine were admitted with
315 symptomatic SARS-CoV-2, and none of the women with a composite indicator for moderate
316 or severe infection had received three vaccine doses according to current recommendations
317 to protect non-pregnant adults against severe omicron infection. Vaccination for all pregnant
318 women regardless of risk group in the UK was recommended from 16th April 2021, and all
319 adults were eligible to receive vaccination from mid-June 2021.¹⁹ Vaccine coverage
320 surveillance among women who gave birth in England up to October 2021 reported that
321 29.4% of the women had received two doses of vaccine and 58.2% were unvaccinated²⁰.
322 Similarly, vaccine coverage has been low in Scotland where 32.2% of women who gave birth
323 in October 2021 had received two doses of vaccine during pregnancy compared to 77.4% of
324 women of reproductive age (18-44 years), and 98.1% of women admitted to the ICU were
325 unvaccinated.⁶ Almost 68% of the women with information about vaccination status included
326 in the current study were unvaccinated.

327

328 In the general adult population, effectiveness after the second dose declines from 60-75%
329 three weeks after vaccination to 20% at 15 weeks and 10% after 25 weeks,²⁰ and three
330 doses have been shown to give better protection against severe disease with the Omicron
331 VOC in adults.²¹ The interval between the last dose and the admission was 3 months or
332 more among half (53%) of the women who had received two doses of vaccine. The number
333 of pregnant women who had received a third booster dose was low in our study, but no
334 severe cases in this group indicates the importance of the third dose to protect pregnant

335 women from both hospital admission with symptomatic covid-19 and need for respiratory
336 support.

337

338 Disproportionate admissions due to covid-19 among pregnant women with ethnic minority
339 backgrounds were less prominent in the current study than previously described during the
340 wildtype period.¹³ National guidance has emphasised the importance of addressing this
341 inequality and advised active health seeking in these groups.¹⁶ The observation time in the
342 current study is short and the findings cannot yet reliably indicate if the smaller differences
343 can be attributed to better communication, prevention, health care seeking strategies or
344 previous infection. Preliminary surveillance results indicated that the Omicron VOC has a
345 secondary attack rate of 10-13% and therefore factors that increase transmission, such as
346 multi-occupancy housing and public-facing occupations, are important also for this variant.²²⁻
347 ²⁴ Since socioeconomic deprivation is also a known independent risk factor for adverse
348 pregnancy outcome, this could be a source of residual confounding in this study.

349

350 Neonatal outcomes were purposely not compared between omicron and other periods as a
351 high proportion of pregnancies were continuing at the time of analysis. However, the
352 available data suggest that the risk of stillbirth during this period may be lower than observed
353 during the delta period⁵. Further follow-up is required to clarify the effect of infection during
354 the Omicron dominant period on perinatal outcomes such as stillbirth.

355

356 ***Implications for clinicians and policymakers***

357 The findings of this study indicate that the risk of severe respiratory failure in unvaccinated
358 pregnant women with Omicron VOC is similar to that observed in the UK during the initial
359 wildtype variant wave of the pandemic.¹³ While severe outcomes were less frequent in the
360 current period compared to the previous Alpha and Delta variant dominant periods, it is
361 important to keep in mind that the risk of hospital admission due to covid-19 was higher in
362 the UK than in other European countries during the initial months of the pandemic,^{25 26}
363 possibly associated with early implementation of public health measures to limit viral
364 transmission. If public health interventions could to some extent protect pregnant women
365 during the first wave, individual protection through vaccination is now available. Our results
366 indicate that most current cases of respiratory failure among pregnant women are
367 preventable, yet vaccine uptake among pregnant women remains low compared to the
368 general female population in fertile age. Continued, strong efforts to improve uptake of the
369 vaccine during pregnancy are still needed. This is of even greater importance as infection
370 continues to rapidly rise in both high and low-resourced settings.²⁷

391 **Acknowledgements**

392 The authors would like to acknowledge the assistance of UKOSS reporting clinicians, the
393 NIHR Reproductive Health & Childbirth National Research Champions, and the UKOSS
394 Steering Committee without whose support this research would not have been possible.

395

396 **Contributorship statement**

397 All authors contributed to conceptualisation, the writing and editing of this study, had final
398 approval of the version to be published and agree to be accountable for all aspects of the
399 work. KB, EM, NS, CG, PO, MQ, PB, JK and MK contributed to funding acquisition,
400 supervision, and methodology. HE, RR, NV, KB and MK contributed to data curation and
401 formal analysis, and had access to verify the underlying data. MK, as guarantor, accepts full
402 responsibility for the work and affirms that the manuscript is an honest, accurate and
403 transparent account of the study being reported; that no important aspects of the study have
404 been omitted; and that any discrepancies from the study as originally planned have been
405 explained. The corresponding author attests that all listed authors meet authorship criteria
406 and that no others meeting the criteria have been omitted.

407 The Corresponding Author has the right to grant on behalf of all authors and does grant on
408 behalf of all authors, a worldwide licence to the Publishers and its licensees in perpetuity, in
409 all forms, formats and media (whether known now or created in the future), to i) publish,
410 reproduce, distribute, display and store the Contribution, ii) translate the Contribution into
411 other languages, create adaptations, reprints, include within collections and create
412 summaries, extracts and/or, abstracts of the Contribution, iii) create any other derivative
413 work(s) based on the Contribution, iv) to exploit all subsidiary rights in the Contribution, v)
414 the inclusion of electronic links from the Contribution to third party material where-ever it may
415 be located; and, vi) licence any third party to do any or all of the above.

416

417 **Funding**

418 The study was funded by the National Institute for Health Research HS&DR Programme
419 (project number 11/46/12). MK is an NIHR Senior Investigator. The views expressed are
420 those of the authors and not necessarily those of the NHS, the NIHR or the Department of
421 Health and Social Care.
