Abstract

Introduction: Medical education and medical education research are growing industries that

have become increasingly globalized. Recognition of the colonial foundations of medical

education has led to a growing focus on issues of equity, absence, and marginalization. One

area of absence that has been under-explored is that of published voices from low- and middle-

income countries. We undertook a bibliometric analysis of five top medical education journals

to determine which countries were absent and which countries were represented in prestigious

first and last authorship positions. Methods: Web of Science was searched for all articles and

reviews published between 2012 and 2018 within *Academic Medicine*, *Medical Education*,

Advances in Health Sciences Education, *Medical Teacher*, and *BMC Medical Education*. Country

of origin was identified for first and last author of each publication, and the number of

publications originating from each country were counted. Results: Our analysis revealed a

dominance of first and last authors from five countries: USA, Canada, United Kingdom,

Netherlands, and Australia. Authors from these five countries had first or last authored 74% of

publications. Of the 195 countries in the world, 53% were not represented by a single

publication. There was a slight increase in the percentage of publications from outside of these

five countries from 22% in 2012 to 29% in 2018. Conclusion: The dominance of wealthy nations

within spaces that claim to be international is a finding that requires attention. We draw upon

analogies from modern Olympic sport and our own collaborative research process to show how

academic publishing continues to be a colonized space that advantages those from wealthy and

English-speaking countries.

Key words

bibliometrics; medical education research; anticoloniality; Global North dominance;

bibliodiversity

Key messages

What is already known on this topic

- Authors from a small number of high income countries are over-represented in published

journal articles on medical education.

What this study adds

- This study shows that almost three-quarters of first and last authorship positions in several

prominent medical education journals are held by authors from only five countries: USA,

Canada, UK, Netherlands, Australia.

- Authors from low- and middle-income countries, and from countries where English is not the

dominant language, are under-represented in prestigious first and last authorship positions

within the medical education literature.

- As a field that claims to be international in scope, perspectives from outside of these five

dominant countries are under-represented, limiting the breadth of views that make up the field

of medical education.

How this study might affect research, practice or policy

- This study provides support for academics, academic institutions, and academic publishers in

establishing policies that prioritize the inclusion of authors from low- and middle-income

countries and from countries in which English is not the dominant language.

-Explicitly including descriptions of the ways research teams address potential power

imbalances in research studies that involve collaboration between HIC and LMIC authors, as

well as fluent English and less-fluent English speakers in English language publications, may

allow further development of more inclusive models of international research collaboration.

Introduction

The global need for well-educated doctors, and other health professionals, who are able to provide high quality health care, is undisputed given the many health challenges societies face in the twenty-first century. Scaling up of health professions education opportunities has been proposed as one means of generating an educated workforce for addressing health system needs and has been a priority of the World Health Organization since the 1950s.[1,2] With global recognition of significant health worker shortages,[3-6] this focus on increasing health worker output is necessary and unsurprising, leading to the creation of many new education programs worldwide.

Rizwan et al.[5,6] recently mapped trends in the globalization of medical education programs: India, Pakistan, China, and Brazil currently house the largest number of medical schools. While medical education programs in LMIC and transitional countries[7] are being established to improve health human resources within home countries, they are also drawing foreign students, both from countries lacking education opportunities and from countries where student selection is highly competitive.[5] Countries in Eastern Europe (such as Poland, Hungary, and the Czech Republic), Russia, Ukraine, and China have increasingly established English language medical education programs to attract international students.[5,6] Similarly, in an attempt to attract learners from Canada and the USA, medical education programs with curricula that emulate the American model have expanded within the Caribbean.[6] As a global phenomenon, educating doctors is a growth industry.

Medical education is generally conceptualised as an academic endeavour, best achieved

through well-planned delivery of science-informed education practices, tools, structures, and

processes.[8] To support this, research in medical and health professions education has become

an area of increasing scholarly attention. This has led to a proliferation of academic activity,

including publications, international conference attendance, and increasing diversity of

professions, perspectives, disciplines, and theoretical approaches being recognized as

advancing new knowledge in the field.[9] In examining the burgeoning literature, it is important

to recognise that medical education research is, by academic measures, a relatively recent area

of scholarship. It first emerged as an academic field in the 1950s in North America at a time

when there was an explosion of scientific medical knowledge, an influx of financial incentives to

support research, and a mandate to demonstrate greater public accountability.[10] As an area of

inquiry, its development was firmly entrenched in Euroamerican healthcare and higher

education structures. The colonial underpinnings of these structures is well documented,

including ways that notions of academic legitimacy are based in biomedicine (which ignore

traditional and Indigenous healing practices which developed in many different global contexts

over millennia[11]) and are inextricably intertwined with European colonization of parts of Africa,

the Americas, and Asia.[11-16] In North America and Europe, Abraham Flexner's 1910 report had

enormous impact, entrenching legitimacy of doctor education in high status university settings,

which led to the closing of non-university-based programs including most that provided training

for women and Black students.[17-20]

Recognising the colonial and Flexnerian foundations of medical education provides a helpful

starting point for examining issues of equity, absence, and marginalization of diverse

perspectives within current structures.[21] In recent years, explorations of representation,

discrimination, harassment, silencing, and power differentials have begun to appear in medical

education journals. Many are written as commentaries and perspectives pieces, providing

reflections on personal experiences and theoretical explorations of ways that dominant

approaches (generally white and Euroamerican-centric) constrain and limit the field.[22-30] There

are some empirical studies examining various aspects of representation within medical

education, with recent attention given to gender, sociocultural, and racial equity within

academic medicine's leadership, student body, and curricula.[31-46] There is also growing

documentation of the paucity of published voices from low- and middle-income countries and

non-English speaking scholars in medical education journals that position their reach as

international.[56–60] This parallels the relative absence of authors from LMIC and non-English

speaking countries in leading academic journals in many other areas of academia, including

health and education.[25, 47–55]

Bibliometric analyses are one way to identify imbalances, and a growing set of papers are

exploring the underrepresentation of authors from outside of North America and Europe.[50, 51,

61,62] Maggio et al.[62] specifically examined authorship of knowledge syntheses by country, with

authors from highly ranked North American institutions being dominant. By categorizing lead

authors by UN region,[63] Buffone et al.[50] found that the majority of authors in the medical

education literature were from North America, Northern Europe, Western Europe, or Australia.

Thomas[51] analysed authorship by country of affiliation over a two-year period, comparing

medical education journals to those in education, medicine, and biomedical sciences. Examining

for all authorship positions, he found that there was greater dominance of authors from the

USA, United Kingdom, Canada, and Australia in medical education than in other areas. While

these studies show that there is an overall dominance of authors from high-income English-

speaking countries, there has not yet been a quantification of *prestigious* authorship positions

by *country*.

In medical education research, first and last author positions are often considered more

prestigious and desirable. For many researchers, numbers of first and last authored

publications contribute to academic recognition including promotions, tenure, awards, salary

support, and access to financial support for graduate students and research projects. In

addition to individual academic accomplishment, regularly publishing in highly regarded

journals in one's field allows authors to engage in academic debates and shape understandings

of which topics are deemed meritorious, noteworthy, and interesting. Powerful voices in these

academic journals thus help to map the academic landscape, drawing boundaries and labelling

worthy areas of exploration. While it is acknowledged that first and last authorship positions

denote a higher level of credit for the work, Hedt-Gauthier et al.[57] found that health research

conducted in Africa, or about Africa, was less likely to have first and last authors from low- and

middle-income countries (LMICs) when the publication included collaborating authors from

high-income countries (HICs).

While well-established guidelines for defining what constitutes authorship exist and are

endorsed by many medical journal editors,[49, 66, 65] guidelines for how authorship positions

should be distributed across authors are underdeveloped. Thatje[66] provided rules of thumb for

determining first and last authorship positions within the natural sciences, noting that

disciplinary and national culture may play a role in how decisions are made. Rees et al.[67]

recently noted that while standards of authorship exist within global health research, they do

not address power imbalances that exist between authors from LMIC and HIC. A recent

consensus statement by Morton et al.[68] provided guidelines for determining author order in

partnerships between LMIC and HIC scholars. However, given the recency of these guidelines, it

is yet to be determined whether they will be incorporated into authorship decisions amongst

partnering researchers in the field of medical education.

We undertook a bibliometric analysis of five top medical education journals to determine which

countries were represented in first and last authorship positions. Our aim was to provide

empirical data about which countries or regions of the world were more or less prominent in

the academic spaces dedicated to medical education. While recognizing that many other

journals, including predominantly clinical journals, also publish medical education research, we

chose to focus on journals specifically designed to publish in this area. Thomas's[51] previous

work was able to capture articles on the topic of medical education that were published within

a broad range of clinical, specialty, and disciplinary journals with scopes not exclusive to

medical education research. We aimed to build upon the work of Thomas[51] and chose to focus

on journals that primarily published within the field of medical education and health

professions education, as they constitute spaces where debates and critiques are intended for

audiences who tend to live and breathe within the sphere of medical education. In doing so,

our aim was to capture the boundaries of a field that asserts to be international in scope.

In addition to conducting this research, we recognized that the process of doing the research

was itself illustrative of issues that may affect publication trends. As a collaborative research

team distributed across four continents, we realised that it is was important to explicitly discuss

issues of power and privilege as part of our analysis meetings. We recognised that we were

working our way through specific and concrete research processes and practices in which issues

of power, voice, legitimacy, and representation were ever-present. As such, we agreed to keep

an explicit focus on our research decisions, processes, and practices with a view to identifying

ways privilege and power were manifest and managed in the shared work. We have included

description of relevant aspects of these reflections in the manuscript, in addition to including a

structured statement on reflexivity, positionality and limitations.

Materials and methods

This study was conducted in two phases. In phase one, the methodology for this study was

conceptualized and designed by the three Portuguese authors (ER, AC, MJC) on this paper. In

July 2018 these authors performed a search of the Web of Science database for citable items

(reviews and articles) that had been published between January 1, 2012 and December 31,

2016 in the five top ranking medical education journals at that time within the categories of

Education and Educational Research; Education; Education Scientific Disciplines; and Health

Care Sciences & Services: *Academic Medicine, Medical Education, Advances in Health Sciences*

Education, Medical Teacher, and *BMC Medical Education*. The resulting dataset was extracted

into Microsoft Excel for data analysis. While Web of Science allowed for the export of author

affiliations for all authors as a single data field, it was not possible to have author affiliation for

first and last authors extracted separately. Consequently, there was the need to review each

item and identify the country of author affiliation for first and last authors (when articles

included multiple authors). Though time consuming, this manual process of identifying country

of origin for each first and last author allowed for a more accurate determination than what

might be expected from assigning country of origin through the use of geocoding tools or

software.[51,69] The number of citable items (reviews and articles) for each country with affiliated

first and last authors were counted: For items in which first and last author had a single

country-affiliation and were from the same country, the item was counted only once. For items

in which first and last authors were from different countries, or for which a first or last author

had multiple country-affiliations, the item was counted the same number of times as the

number of countries that were listed. Articles were counted separately for each year and for

each journal. This allowed for further evaluation of longitudinal variations over the eight years

of study and between publication sources. While some bibliometric studies include only a sub-

sample of publications, our inclusion of all published articles allowed for an extremely accurate

count of first- and last-authored publications originating from each country.[51]

Preliminary results from phase one were presented by the Portuguese team at the AMEE 2018

conference.[70] A few years later, this paper's co-first authors were writing a commentary for

which we wanted to cite the results presented at the conference. We learned that the

Portuguese-led work had not yet been able to move forward for publication (limited local

research resources and extra work required for authors from a non-English first language

setting), and, with approval of the Portuguese team, found resources in Canada to update the

search and move manuscript writing forward. While acknowledging that the ability to advance

the work was—ironically and problematically—contingent on specific high income country (HIC)

resource availability, we agreed that continuing this empirical work on publishing inequities was

important. In addition of two Canadians to the Portuguese team, we also embraced the

opportunity to include team members from Ethiopia and Brazil, as respected colleagues and as

part of a commitment to ensure representation of low and middle income country

perspectives in research being done about global research imbalances.

In phase two of this project, the reconstituted team decided to update the data collection,

adding years 2017 and 2018 to the dataset, while following the same methodology as the

original strategy. While we were aware that journal rankings within the field of medical

education had shifted since phase one of the study, we opted to limit our analysis to the five

journals originally identified to ensure consistency in methodology and in recognition of the

longstanding role these journals have played in shaping the field. All aspects of data extraction,

assignment of country of origin for first and last authors, and counting techniques were

replicated from the earlier analysis. Final analyses treated data from both phase one (years

2012-2016) and phase two (years 2017-2018) as a single dataset. Data analyses were conducted

using Microsoft Excel and differences in proportions were compared using 95% confidence

intervals.[71,72] No institutional ethics review was sought for this work since it did not involve

human subjects. Neither patients nor the public were engaged in the study design, conduct,

reporting, or distribution plans of the research. The datasets used and analysed during the

current study have been archived as supplementary files.

Results

5,468 articles were extracted from Web of Science and country of origin was assigned to first

and last authors based on listed institutional addresses. After articles were counted multiple

times to reflect multiple geographic affiliations for first and last authors, 6,173 unique items

remained for subsequent analyses.

At the time of writing there were 195 countries in the world, including 193 UN Member States,

the Holy See, and the State of Palestine.[73] For these 195 countries, across all five journals and

seven years of analysis, the number of first or last authored publications originating from each

country ranged from zero to 1,936. Over 53% of countries were not represented by a single first

or last authored publication, approximately 10% were represented by a single first or last

authored publication, and under 4% were represented by more than 100 first or last authored

publications (see Table 1).

The five countries with the greatest proportion of first and last authored publications included

the USA with 1,936 (31.4%) publications, Canada with 878 (14.2%) publications, the UK with

721 (11.7%) publications, Netherlands with 532 (8.6%) publications, and Australia with 494

(8.0%) publications (see Table 2). Figure 1 shows the percentage of all publications with first or

last authors from these five countries, and the remaining percentage (26.1%) of publications

that originated from all "other" countries combined. Together, these "big five" nations of USA,

Canada, UK, Netherlands, and Australia contributed 73.9% of all first and last authored

publications across all journals and years of study. Figure 2 further shows the number of

publications originating from each country across the globe between 2012 and 2018.

The inequitable presence of first and last authored publications from these "big five" Global

North countries was not evenly distributed across the five medical education journals.

Furthermore, there was a strong positive relationship between the impact factor (2018) of each

journal and the percentage of articles that were published by first and last authors from these

five dominant countries. For example, in 2018 (when our data collection ended), of the five

journals studied, *Academic Medicine* had the highest impact factor at 4.937 and the highest

percentage (96.1%) of articles with first and last authors from these five dominant countries

(Table 2). *BMC Medical Education*, on the other hand, had the lowest impact factor at 1.87 and

the lowest percentage (51.2%) of articles with first and last authors from these same countries

(Table 2). Impact factor is considered one measure of prestige within academic publishing,[74]

and these results suggest that only a small number of countries are represented in first and last

authorship positions within prestigious journals.

While most of our analyses combined years 2012 to 2018 together, we also looked at how the

percentage of first and last authored publications from "other" countries outside of the USA,

Canada, the UK, Netherlands, and Australia had changed over time. Across all journals, there

was a slight increase in the percentage of first and last authored publications from "other"

countries from 22.4% (95% CI 19.5-25.4%) in 2012 to 28.7% (95% CI 25.8-31.5%) in 2018. While

this significant increase in publications from countries outside of the dominant five is

encouraging, the overall proportion of publications from other countries remains low.

Discussion

Our data revealed a dominance of first and last authors from five countries in five top ranked

journals within the international field of medical education. Being a bibliometric analysis, the

results do not provide an explanation for why there is such significant dominance by these five

countries. Also, as we did not include middle authors in our research design, there may be

greater presence of authors from the other 190 countries of the world than we were able to

capture by looking only at first and last authorship positions. Nevertheless, the prominence of

five countries in prestigious authorship positions is a finding that requires attention. While our

research was not designed to identify how this dominance compared to other fields, Thomas[51]

previously found that there were greater geographic disparities within medical education

research than within education, medicine, and the biological sciences. Our current research

reiterated this pattern when analyzing prestigious authorship positions. Our study only included

articles that had been published in the five medical education journals which had the highest

impact factor at a single point in time in 2018. As a measure of journal importance, impact

factor is only one metric, and one that is in constant flux. Future research might expand upon

our strategy and include additional journals that publish on the topic of medical education,

including journals which have experienced a significant increase in impact factor since we first

devised our research strategy in 2018.

Tracking and decision-making about country assignation in bibliometric research is not always

straightforward. As evidenced in previous bibliometric studies, there are many ways in which

geographic origin might be determined. For the current study, we chose to double, or even

triple-count publications as unique items when first or last authors claimed affiliations in

multiple countries. In some instances, this led to confusion in determining whether an author

had more authentic cultural connections to the Global North or the Global South. We view this

as a limitation of the bibliometric nature of our study: in quantifying the geographic

representation of first and last authors, we were unable to more meaningfully determine the

cultural perspective from which each author was writing.

As an international research team deliberately designed to include representation from HICs

and LMICs across several continents, we tried to be reflexive as we collectively advanced this

project. We explicitly discussed aspects of the research process in our meetings. It was readily

apparent that access to academic resources (both material resources and time) significantly

shaped the research process. This included the fact that one of the Canadian authors holds a

research chair that was able to provide funds for the second phase of data collection. The two

Canadian authors therefore had more protected time to advance this project, which in and of

itself is evidence of unearned privilege and showcases research inequities. As a team, we

discussed this fact, recognized that it materially influenced the research process, while aiming

to watch that it did not manifest as greater voice for these authors. We also saw this privilege

as requiring greater responsibility from the Canadian authors to do the "heavy lifting" in order

to move the project forward. The team also discussed the fact of English language fluency

(including the genres of academic writing) and the extent to which that made the writing

process more efficient for the Canadian authors to lead. We recognized that no matter how

careful we were, the fact of writing in English made it easier for the Canadians to shape the

words, and spent time discussing details of language in our meetings. The team decided that it

was acceptable for the Canadian authors to update the preliminary research of the Portuguese

team. Given both time and English language facility, the Canadian authors also led the process

of manuscript writing, with the other team members making substantial edits and comments.

In discussions about authorship order and thinking about contributions and ICMJE guidelines,[64]

we initially thought it might be most appropriate to have a Canadian first author and

Portuguese last author based on currently accepted publishing practices and given the role that

MJC had played in the original design of the study. The irony of producing a manuscript in this

space with a "big five" first author was not lost on us, and we sought options to publish in other

spaces that would acknowledge the significant work of authors less easily represented in

current criteria. We know that HIC academics' ability to engage in critical global work is

significantly enabled by their learnings from and relationships with LMIC academic colleagues.

Current authorship guidelines do not fully recognize this invisible labour on the part of LMIC

academics, but as a team we decided that it was critical to incorporate these contributions into

authorship decisions. As a result, we determined that co-first authorship by a LIC and HIC

academic on the team was the most accurate representation of authorship. The need for such

conversations further highlights the structural issues that determine who can play the sport of

international academic publishing. The fact that our effort to showcase structural inequities in

academia had the potential to lead to the reproduction of dominant voices is telling. In thinking

about ways to increase representation in medical education research, it is clear that neither

recognition of inequities nor good intentions will in and of themselves lead to structural

change.

Attention to privilege and power across all aspects of a research project can lead to different

conversations and different choices, with potential to help trouble assumptions that maintain

HIC academic dominance. Engaging in these processes is essential; it also requires an effort

that in many cases will slow research output. We believe that this "extra" work is necessary to

improve knowledge creation and as a way to advance appropriate models of HIC-LMIC

collaborative research practice. We also realise that this form of academic activity is not

currently recognised in terms of academic metrics, and know there is more to do to find ways

for such work to be valued.

The dominance of wealthy nations within spaces that claim to be international, though

troubling, is not unique to medical education, the health professions, or academia in general.

The prominence of the "big five" countries in medical education research brings to mind the

colonization of many Global South countries during the 19th Century when Global North

sportsmen hunted for "big five" trophy animals: elephants, lions, rhinos, leopards, and buffalo.

Symbolically, the hunting of big game in Africa and India served the purpose of solidifying the

triumph of colonists over those being colonized.[75] As a more modern sporting analogy, we are

reminded of the Tokyo 2020/1 Olympic and Paralympic games, an event that represents one of

the world's largest international sporting events. Within the popular media, Tokyo 2020/1 was

touted as one of the most equitable games in history. However, of the 206 nations and

territories competing at the games, 98 countries had less than ten athletes participating. In

contrast, the games were host to 613 athletes from the USA, 552 from Japan, 478 from

Australia, 425 from Germany, 406 from China, 398 from France, 376 from Great Britain, 372

from Italy, and 370 from Canada.[76]

Rather than being a recent phenomenon, modern Olympic history, especially after World War I,

has been described as paradoxically espousing universal ideals and providing an opportunity for

the colonized to participate and win against the colonizers, while simultaneously reinforcing

exclusionary, elitist, and racist practices.[77] Houghton[78] traced the history of the inclusion of

Indigenous Latin American athletes and other "recently conquered" Indigenous peoples in the

early Twentieth Century Olympics. In addition to participating in primitive sideshows that were

aimed at showcasing the "barbaric" sporting practices of Indigenous tribes, these Indigenous

peoples were also then made to compete alongside developed nations in modern Olympic

events that set themselves up for ridicule, infantilization, and as a way to prove the inferiority

of Global South nations.[78] Of course, decisions about "what counts" as an Olympic sport also

contribute to the dominance of wealthy nations. Sports with long colonial histories, such as

football and athletics[79] continue to be included, as do sports with more recent histories that

rely on extensive and expensive sporting infrastructure, such as velodrome cycling,

bobsledding, and sailboat racing. However, traditional African sports such as Nguni (stick

fighting), Capoeira, donkey-racing, and Dambe boxing continue to be absent, despite

recognition of their value to local peoples.[80] We draw attention to this sporting analogy to show

not only that North-South disparities are omnipresent and surreptitious, but that they are also

engrained in structures and inequities that are built upon historical and colonial roots that

continue to be perpetuated through international spaces, even those that aim to unite

humanity and have the allure of being inclusive.

In comparing medical education research to the Olympics, we hope that looking at structures

elsewhere may open up new ways of seeing a space we take for granted. Bourdieu[81] effectively

examined sport as a way to highlight that in every sphere there are philosophical underpinnings

that are inherently political. Bourdieu also emphasized social spheres as spaces of conflict and

struggle, including the field of science.[82] Albert and Kleinman[83] drew upon Bourdieu's concepts

in suggesting that it was necessary to understand how interactions that may appear to be

based on cooperation may more accurately reflect domination and subordination. More

recently, Martiminanakis et al.[83] drew attention to the need to consider the inevitable

knowledge politics that inform discussions about research quality and rigour within medical

education. We suggest that representation in the academic literature is an area which would

benefit from further exploration of the ways knowledge politics shape what is considered

legitimate in these spaces. Acknowledging the skewed proportion of authors from different

countries does not lead directly to solutions designed to "add" voices from LMICs without

attention to the historical and colonial roots from which disparities have developed.

This leads to some potentially uncomfortable questions. For HIC researchers, it is pleasing to

consider academic conversations with peers from other HICs to constitute international

debates. But is it possibly a conceit to think that medical education research in its current form

is truly globally relevant? To what extent is the new knowledge being shared in academic

publications able to be implemented and evaluated in lower resource settings? Are important

knowledges excluded from currently accepted content in medical education journals? How

relevant is the content of top medical education journals in diverse contexts? How willing might

HIC academics be to probe the layers of privilege that serves them well in terms of impact

factor, academic promotions, and claims of international recognition? Beyond individuals, are

HIC academic institutions open to questioning the structures that maintain their high

international rankings? LMIC academic institutions are also driven by academic rankings so

individual LMIC researchers may be encouraged to preferentially aim for international journal

publications. A related issue explored by others[84,85] is how researchers from non-English

speaking countries make choices about when to publish in "international" English-language

journals versus reaching audiences in their own country and language. These are not decisions

that English-language country researchers need to make, adding to the burden placed on those

academics. The concept of bibliodiversity (or diversity in scholarly publishing)[86, 87] has been

adopted by Global South authors as a way of supporting the decolonization of Southern

knowledge,[88] and multilingual publishing may be one way that bibliodiversity can be achieved.[89]

Conclusions

There have been a recent series of calls to action and incisive analyses, most prominent in

critical global health spaces,[29,47,49,57,59,90,91] but also in medical education journals,[30,46,50,51,62,92]

that are contributing to a body of literature that demonstrates the ways academic publishing

structures continue to privilege HIC academics. Continued conceptual and empirical work in

these spaces is essential. It is also important to ensure that academics from diverse contexts

are included in teams undertaking this work, and that in these collaborations close attention is

paid to privilege, voice, and representation.

As a research team we believe that we must start and sustain these conversations across all

aspects of our scholarly work. HIC academics, academic institutions, and academic publishers

must not view the opening of cracks into privileged spaces as a way of being "nice" or as proof

of benevolence. There is an ethical and moral imperative to examine and disassemble colonial

structures. A recent call from the United Nations Educational, Scientific, and Cultural

Organization (UNESCO)[93] and the International Science Council[89] compels us to consider

scientific advancement a global public good to which open access is required. Eight

recommendations were recently endorsed by the International Science Council,[94] including

ensuring that new scientific knowledge is accessible to all without limitations based on

institutional privilege, geography, an ability to pay, or language. UNESCO also calls for more

collaborative and inclusive scientific practices aimed at the achievement of the Sustainable

Development Goals[95] and reducing global inequities.

HIC also have much to learn from LMIC colleagues, and must find the humility and will to listen.

As HIC countries face severe health human resource shortages, there will be learnings from

LMIC colleagues who have chronically grappled with these issues. Many LMIC countries

spectacularly outshone HIC countries in effectively managing successive waves of the COVID-19

pandemic[96,97] with far fewer resources. With growing recognition of the limits of Euroamerican

biomedical approaches to healthcare, making academic space for traditional knowledges from

many global contexts, as well as deep examination of the effects of colonization on health, are

opportunities we must embrace. For science to be universal, it must be inclusive of a wide

range of global knowledges.[94] If scholarly medical education communities are willing to re-

envisage the rules of the game to focus on ways we can be faster, higher, and stronger

together, we may better harness the transformative aspects of education to contribute to a

healthier world.

contributions to the interpretation of the data. DW,CW, CC, MJC drafted this manuscript, and

ER, AC, TSL critically reviewed the manuscript for intellectual content. All authors approved the

final version of this manuscript, agreed to being accountable for all aspects of the work, and to

investigating and resolving any questions that arise in relation to the accuracy and integrity of

this work.

Reflexivity statement

This research was conducted by an informal partnership of authors from high-income countries,

low- and middle-income countries, countries where English is the dominant language, and

countries where the dominant language is other than English. Throughout the study,

conversations were held during team meetings to discuss inequities that existed across team

members in terms of available funds, time, and personnel for conducting and writing up the

findings of this research. When deciding on an appropriate authorship order, we were guided

by both the ICMJE guidelines and by the Consensus statement on measures to promote

equitable authorship in the publication of research from international partnerships. We also

acknowledge that authorship guidelines can at times be used to advantage authors with greater

material resources to contribute to a project, and that English language fluency greatly

advantages English as first language authors in making claims to authorship position. As a team,

we recognised that we were able to have ongoing and sometimes challenging conversations

about the ways privilege and power needed to be examined in mundane research practices

because of pre-existing trusting relationships. CW and DW have worked together for many

years. TSL spent a year as a visiting scholar in Canada working with CW. Both DW and TSL have

worked closely with CC on research projects. MJC, ER, and AC are Portuguese colleagues at the

same institution and led the initial stage of the research project. MJC and CW had built a

collegial relationship through conversations at international medical education conferences.

Funding

This study did not receive external funding but did receive support from Cynthia Whitehead's

BMO Chair.

Competing interests

Cynthia Whitehead is the holder of the BMO Financial Group Chair in Health Professions

Education Research at University Health Network. No other authors have any competing

interests to declare.

Ethics approval

No institutional ethics review was sought for this work since it did not involve human subjects.

Data Availability

The datasets generated and analysed during this study have been archived as supplementary
