26 **Abstract**

27 Social support is deemed to have a crucial influence on maternal health and wellbeing during
28 pregnancy. The objective of the study was to explore the experiences of pregnant young females
29 and their receipt of social support in Soweto, South Africa. An interpretive phenomenological
30 approach was employed to understand and interpret pregnant young women's lived experiences of
31 support networks on their pregnancy care and wellbeing. Data was collected conducting 18 indepth
32 interviews with young pregnant women. Analysis of the data resulted in the development of two
33 superordinate themes: (1) relationships during pregnancy and (2) network involvement. Each
34 superordinate theme was linked to subthemes that helped explain whether young women had
35 positive or negative experiences of social support during their pregnancy care, and their wellbeing.
36 The sub-themes emanating from the superordinate theme 'relationships during pregnancy' were
37 (a) behavioural response of partner following disclosure of pregnancy, (b) behavioural response
38 of family following disclosure of pregnancy, and (c) sense of emotional security. Accompanying
39 subthemes of the superordinate theme 'network involvement' were (a) emotional and instrumental
40 support, and (b) information support. An interpretation of the young women's experiences has
41 revealed that young women's satisfaction with existing support networks and involvement of the
42 various social networks contributed greatly to the participants having a greater sense of potential
43 parental efficacy and increased acceptance of their pregnancies. Pregnant women who receive
44 sufficient social support from immediate networks have increased potential to embrace and give
45 attention to pregnancy-related changes. This could, in turn, foster positive behavioural outcomes
46 that encourage engaging in good pregnancy care practices and acceptance of motherhood.

47 Focusing on previously unexamined factors that could improve maternal health, such as social
48 support, could improve maternal mortality rates and help achieve reproductive health accessibility
49 universally.

66 **Introduction**

67 Social support has been reported to play a crucial role in maternal health and wellbeing (1),
68 influencing individuals' ability to cope with events during specific periods (2). Social support is
69 characterised by the manner in which connections that exist between people who have recurring
70 interactions, fulfil the needs of individuals and this form of support can exist in an emotional,
71 instrumental, affectionate or tangible form (3). The prenatal period is considered to be a delicate
72 time particularly in view of the emotional, psychological and social wellbeing of expectant
73 mothers (4). Pregnancy is generally viewed as a period that is coupled with various physiological
74 and emotional changes, and these changes can have significant effects on both maternal and infant
75 health outcomes (5-9). Close relations with other individuals play an integral role in influencing
76 the quality of life of individuals which promotes positive wellbeing, subsequently resulting in
77 expectant mothers perceiving pregnancy-related changes as less stressful (10). Thus, the care and
78 support that pregnant woman receive contributes greatly to how they experience their pregnancy
79 (11, 12).

80

81 A vast body of empirical evidence has been documented on the influence that social support has
82 on the depressive symptoms that expectant women experience such as antenatal depression,
83 postpartum depression, and subjective wellbeing amongst others (13-21). In particular, women
84 who experience a lack of social contact or connection with others, and also perceive themselves to
85 have low social support, have increased susceptibility to anxiety and antenatal depression,
86 particularly if they have a strained relationship with their partner or family, which can subsequently
87 affect various developmental outcomes of their babies (2, 22-30). Thus, social support may result

88 in reduced risks of depression during pregnancy subsequently resulting in positive pregnancy and
89 health outcomes (31).

90
91 Empirical evidence has shown that expectant mothers need support that involves undertaking
92 tangible acts or activities, monitoring and care which promotes positive wellbeing and health for
93 both mother and child (32). In addition, social support is deemed as important in strengthening
94 positive health outcomes in families experiencing events that involve significant changes to their
95 lifestyles such as the birth of a child or rearing of children (4, 33). Of note, significant differences
96 have been observed with respect to the degree of social support received by adolescent mothers
97 who are in the age groups 15 to 19 years and that of older mothers who are between the age groups
98 25 and above (23, 27), with results indicating that adolescent mothers received lower levels of
99 social support than older mothers due to their weakened capability to create and sustain close
100 connections and social ties with other individuals (23, 27). Despite the prevalence of adolescent
101 pregnancy being largely documented in South African literature, stigmatization of adolescent
102 pregnancy in the country remains rife (34). Empirical evidence has shown that stigmatization of
103 adolescent pregnancy has the potential to weaken or compromise an adolescent's social support
104 systems, which influences the health of both the child and adolescent mother (35, 36).

105
106 Although there are various studies, particularly from high-income countries, that have examined
107 social support during pregnancy (31, 37-39), most studies have been limited to adolescents or older
108 mothers and most have examined social support from a quantitative perspective while there is a
109 dearth of phenomenological inquiry that captures the lived experiences of social support through

110 the in-depth narrative accounts of pregnant women. Additionally, studies that exist on social
111 support have focused on partners' role on the health of young mothers which has been limited to
112 paternal involvement defined only through the state of being married or not married or the
113 inclusion of the name of the father on the child's birth certificate (6, 40-43). Moreover, most
114 studies that focus on partner support have not been able to explain partner involvement and
115 pregnancy outcomes as well as the type of support that partners offer, through more in-depth
116 narrative accounts (6, 44, 45).

117
118 The potential role that families play in childbearing practices of young women merits further
119 research given that the majority of South African adolescent and young women have been reported
120 not to be in a marital union and are also resident in their families' households during their
121 pregnancy (46). Furthermore, several international studies have conducted research on social
122 support initiatives that are specifically run by expectant mothers as well as professional initiatives
123 during pregnancy (4, 47-52) leaving a gap regarding other forms of social support, such as family
124 and peer support. The findings of these previous studies have shown that expectant females have
125 obtained support from their peers and a therapeutic space in these support groups which has played
126 a significant role in positive pregnancy outcomes and positive emotional wellbeing. In addition,
127 pregnant women have received professional support through individualised education and
128 supportive phone calls and other forms of support which are emotional, affirmational,
129 informational and practical from both mother-to-mother support groups and healthcare providers,
130 resulting in improved Quality of Life (QoL) during pregnancy (49). Also, receipt of social support
131 has been mostly evident following the birth of a child (53). However, the need for social support
132 is greater in the prenatal period.

133
134 It remains unclear what type of support is received by expectant mothers from low- and middle-
135 income country settings, in particular young women, as there is limited literature on the social
136 support patterns on the wellbeing of this specific age group and a lack of in-depth understanding
137 of their relationships. Given this background, the study's objective was to explore the lived
138 experiences of young females' receipt of social support and how it relates to their pregnancy care
139 and wellbeing during the prenatal period, through a phenomenological approach, in the context of
140 a South African township called Soweto.

141

142 **Materials and methods**

143 **Study design**

144 An interpretive phenomenological design was employed in this study. The rationale for employing
145 this approach is that its philosophical and methodological foundations in phenomenology seek to
146 offer in-depth insight into the experiences of individuals through describing, comprehending and
147 interpreting participants' experiences (54-56). Of note, individuals' experiences are influenced by
148 the world they live in, including certain determining factors in their lives which are often linked to
149 social, cultural or political contexts (57). Thus, interpretive phenomenology was suitable in this
150 context as it assisted in gaining insight into young women's lived experience of receipt of social
151 support regarding pregnancy care and wellbeing during pregnancy. Furthermore, this approach
152 involves using semi-structured interviews and in-depth interviews and allows the researcher to
153 search for meaning in the narrative accounts of participants (58).

154 This phenomenological view thus enables the researcher to try to make sense of the participant's
155 experience whilst gaining insight into the participant trying to make sense of what they have
156 experienced (59). Moreover, the phenomenological method contributes significantly to the
157 analysis of study participants' narratives as it helps reveal the inner meaning or essence of a
158 phenomenon (60). The phenomenological method employed here involves three central
159 components: (1) bracketing, (2) analysis using imagination and instinct (3) describing (61).
160 Bracketing implies that the researcher has preconceived notions, experiential knowledge or has
161 certain expectations about the phenomenon under study but does not apply these elements during
162 investigation (60).

163
164 Bracketing in this study was however applied by putting aside the researchers' knowledge and
165 beliefs about the phenomenon under study in order to accurately capture and describe the
166 participants' experiences. In terms of imagination and intuition, the researcher examines the
167 phenomenon under study open-mindedly and the process of describing involves explaining or
168 describing a phenomenon as accurately as possible without depending on any pre-given framework
169 (62).

170

171 **Setting**

172 The study took place at the Chris Hani Baragwanath Academic Hospital located in Soweto,
173 Johannesburg, South Africa. It is nested in the Healthy Life Trajectories Initiative (HeLTI), and
174 specifically the "*Bukhali*" randomised control trial that examines the effects of a complex
175 intervention aimed at optimizing the health of young women preconception, during pregnancy,

176 and postnatally (63). Soweto is a historically disadvantaged and underprivileged high-density peri-
177 urban area that lies in the outskirts of the city of Johannesburg, with 1.3 million residing in the
178 area (64). Although Soweto is characterized by diverse economic structures and activities, poverty
179 related challenges remain rife in the area with food insecurity and unemployment being highly
180 prevalent (65). The majority of the population residing in Soweto is deemed to have poor or limited
181 access to appropriate healthcare services, particularly, youth-friendly services (66). Soweto is an
182 area that can be deemed to be largely characterized by patriarchy in which gender inequality and
183 harmful gendered stereotypes dominate childbearing decisions of young women (67-69).
184 Additionally, the introduction of various health initiatives among young women during their
185 reproductive years is pivotal given that 33% of young women will experience adolescent
186 pregnancy and give birth to their first child before their 19th birthday.

187

188 **Eligibility and participant recruitment**

189 The study adopted a purposive sampling approach as it assisted in selecting participants who share
190 similar characteristics and meet the selection criteria. Eighteen pregnant participants who were in
191 the age groups 18 to 28 years, were recruited from the *Bukhali* trial and were interviewed.
192 Participants assigned to the intervention arm received health literacy material pertaining to
193 physical and mental health, micronutrient supplements, and free access to HIV and pregnancy
194 testing. The intervention is delivered monthly by community health workers over a period of up
195 to 18 months' preconception, and continuing into pregnancy. Pregnancy specific material is
196 provided to address healthy diet and healthy behaviours during pregnancy, and antenatal care

197 activities that pertain to birth preparation and the child's arrival (63). Participants in the control
198 arm received information related to life skills and are also offered free HIV and pregnancy testing.
199 Participants who had experienced a pregnancy loss were not recruited for this qualitative study.
200 Due to the current blinding of the trial, combined results are reported for intervention and control
201 participants.

202

203 **Data collection**

204 Participants participated in individual in-depth interviews in the month of August 2021 at the
205 research centre within the precinct of Chris Hani Baragwanath Academic Hospital in Soweto.
206 Interview guide questions were developed by the study team and used for prompting where
207 necessary. Interview questions focused on young women's pregnancy experiences, support
208 structures, health behaviours (antenatal care visits) and sources of information on pregnancy. Two
209 local female interviewers fluent in both English and other South African vernacular languages
210 conducted the interviews. Following COVID-19 safety protocols, the participants were
211 interviewed in person in a comfortable and silent room that offered maximum privacy. An audio
212 recorder was used and the interviews lasted between 45-60 minutes; notes were taken during each
213 session in order to document key narratives and participants' non-verbal cues. Prior to analysis,
214 the recorded narratives of the participants were transcribed verbatim and interviews that were
215 conducted in the participants' native language were translated into English.

216

217 **Data analysis**

218 Colaizzi's seven-step method was used to analyze the data with the aid of MAXQDA software
219 version 2020 (70) which assisted in recording and coding the interview transcripts. However, only
220 six steps were employed in this study given that follow-up interviews did not take place in the
221 seventh stage in order to validate our findings from the study participants. Colaizzi's method is an
222 inductive method used in phenomenology that assists in selecting prominent assertions, classifying
223 and thinking logically of the meanings of the event or outcome being investigated as well as
224 describing and depicting the participants' experiences (71, 72). In the first step, we first checked
225 the transcripts against the recordings and revisited the content so as to make sense of the lived
226 experience of all the individual participants and to comprehend the feelings and thoughts of the
227 young pregnant women. Next, we extracted significant phrases and statements from the transcripts
228 that form a complete meaning of each participant's experience. This was done by further re-reading
229 each transcript in order to point out prominent assertions from each interview transcript. We then
230 wrote separate assertions for each individual. In the third step, we formulated more general
231 meanings from each significant statement on the text. We then coded and categorized these
232 meanings from the various transcripts and checked for consistency of the meanings across all
233 transcripts. In the fourth step, after acquiring meanings emerging from the prominent assertions,
234 we then arranged meanings into thematic clusters. Accompanying subthemes are shown in Table
235 1.

236

237 Two superordinate themes were developed from the cluster of themes that adequately explained
238 young women's experiences of social support on pregnancy care and wellbeing. Superordinate

239 themes and sub-themes were developed by mapping interrelationships, connections and patterns
240 across the narratives through engaging with the recordings and revisiting each transcript several
241 times. Several phrases were coded, and important phrases were identified resulting in the
242 generation of the superordinate themes and sub-themes. In addition, for each superordinate theme,
243 specific extracts for that theme were selected from different participants and placed under each
244 relevant theme. This assisted us in achieving internal consistency and relative broadness of each
245 superordinate theme. In the fifth step of analysis, we integrated all emerging themes into
246 descriptions of the event or outcome being examined. This was done by bringing together all the
247 thematic clusters, superordinate themes and generated meanings to create a structure that expressed
248 the meaning in each theme (Table 1).

249 **Table 1. Themes focusing on young women’s experiences of social support on pregnancy**
250 **care and wellbeing.**

Superordinate theme	Sub-themes
1. Relationships during pregnancy	1.1. Behavioural response of partner following disclosure of pregnancy 1.2. Behavioural response of family following disclosure of pregnancy 1.3. Sense of emotional security
2. Network Involvement	2.1. Emotional and Instrumental support 2.2. Information support (medical and cultural information support)

251

252 **Ethical Statement**

253 Approval to conduct the study was granted by the Human Research Ethics Committee (Medical)
254 based at the University of the Witwatersrand (M190449). Participants were requested to sign an
255 informed consent form which stipulated the aims of the study, guaranteed confidentiality and
256 indicated that the study is voluntary. The informed consent form also provided information on who
257 would have access to the participants' information, indicated that the study was voluntary, and
258 provided information on the storage of data, recording of data and the dissemination of the
259 findings. All participants who were willing to participate voluntarily and fully acknowledged that
260 they understood the purpose of the research written permission to be interviewed, and for the
261 narratives to be recorded.

262

263 **Results**

264 All 18 participants were between the age groups 18 to 28 years. Overall, three participants had a
265 primary school qualification, ten had a secondary school qualification, two had a tertiary
266 qualification and three participants did not complete their primary education. Only six participants
267 were enrolled in a higher education institution. Almost all females (16) indicated being in a
268 relationship when the interview took place with only four of the participants living or cohabiting
269 with their partners and 14 living with their families. Nine young women reported that they had
270 given birth before, with the current pregnancy being their second pregnancy. Sociodemographic
271 details are provided for each participant in Table

272 2.

Table 2. Demographic Profile of the participants.

Participant code	Current age	Highest level of education attained	Currently enrolled in Higher Education Institute	Employment status	Lives with	Relationship status	Number of pregnancies
Participant 1	21-25	Secondary school qualification	Yes	Unknown	Parents and siblings	In a relationship, not living together	1
Participant 2	21-25	Secondary school qualification	No	Unemployed	Partner	In a relationship, and living together	1
Participant 3	16-20	Secondary school qualification	No	Unemployed	Parent and siblings	Single	1
Participant 4	16-20	Primary school qualification	No	Unknown	Parent, relative and siblings	In a relationship, not living together	2
Participant 5	16-20	Primary school qualification	No	Unemployed	Grandparent and relative	In a relationship, not living together	1
Participant 6	21-25	Primary school qualification	No	Employed	Sibling	In a relationship, not living together	1
Participant 7	21-25	Tertiary qualification	Yes	Unemployed	Parent	In a relationship, not living together	2
Participant 8	21-25	Secondary school qualification	No	Unemployed	Partner	In a relationship and living together	2
Participant 9	16-20	Some primary school	No	Unemployed	Parent and sibling	In a relationship, not living together	2
Participant 10	21-25	Secondary school qualification	No	Unemployed	Parent and siblings	In a relationship, not living together	2

Participant 11	21-25	Secondary school qualification	No	Unemployed	Child	Single	2
Participant 12	21-25	Tertiary qualification	Yes	Employed	Partner	In a relationship and living together	2
Participant 13	21-25	Some primary school	No	Unknown	Partner	In a relationship, and living together	1
Participant 14	21-25	Secondary school qualification	Yes	Employed	Parent	In a relationship, not living together	1
Participant 15	21-25	Some primary education	No	Unknown	Parent and relative	In a relationship, not living together	2
Participant 16	16-20	Secondary school qualification	Yes	Unknown	Parents and relatives	In a relationship, not living together	1
Participant 17	16-20	Secondary school qualification	Yes	Unknown	Grandparents	In a relationship, not living together	1
Participant 18	26-30	Secondary school qualification	No	Unemployed	Child	In a relationship, not living together	2

1. Relationships during pregnancy

1.1. Behavioural response of partner following disclosure of pregnancy

The narratives of the participants indicated that most of the participants' pregnancies were unplanned. Despite this, most participants reported feeling happy about their pregnancies. Participants described feeling surprised and shocked when they learned about their pregnancy, and their subsequent meaning-making about their pregnancies tended to reflect overall relationship dynamics. The young women were worried about disclosing the pregnancies to their partners and feared getting negative reactions. However, many of the young women reported that their partners responded with great happiness and joy to the news of their pregnancy and their relationships with their partners remained stable. Thus, the partners' behavioural response made the young women feel supported and safe in their relationships, fostering feelings of happiness and acceptance of the pregnancy and translating into positive wellbeing for the participants.

“Things are fine between me and my partner, normal as before. Since he accepted, he feels like he is okay, because he is also very supportive.” (Participant 1, 21-25 years old).

“He is also excited because it's what he's been hoping for and to him it's the first child. We're all okay, and also we stuck together, he's supportive. We stay together, we do all things together, we're not apart; only if he's at work. Like we're all on the same page.” (Participant 2, 21-25 years old).

286 One of the young women's narratives showed that her partner's family had wanted her to fall
287 pregnant which led to plans of marriage, although the young woman had not actually married her
288 partner when the interview took place.

289 *"The pregnancy was something that they wanted to plan, yeah, because the guy came to our*
290 *home and took out some, it's not lobola [customary payment for marriage], but he was just*
291 *introducing himself and his family"* (Participant 6, 21-25 years old).

292 However, contrary to these findings, other participants indicated that their relationships with their
293 partners changed following the disclosure of their pregnancy, as their partners' reactions changed
294 how the women viewed the relationship as opposed to how they viewed the pregnancy. Partners
295 distanced themselves from the young women resulting in a dissolution of the relationship. Such
296 circumstances resulted in the young women having negative wellbeing and not accepting their
297 pregnancies.

298 *"My relationship with my partner was fine, until I was pregnant. I told him about the*
299 *pregnancy and he did not want to be involved, and I just cancelled him out of my life."*
300 (Participant 3, 16-20 years old).

301 *"I told the child's father that I am pregnant then he decided that we should stop seeing each*
302 *other. He said to me in March, he does not want this child, he won't be able to help me so*
303 *it's best that I get an abortion, so I asked him that when I get an abortion, am I supposed*
304 *to do it alone, because after that you have to get me cleansed, and then he said to me that*
305 *I will find my own way, he is not interested, I must just leave him alone."* (Participant 4, 16-
306 20 years old).

307

308 Another distinctive feature emerging in one of the narratives showed that although the young woman was
309 receiving instrumental support from her partner, she had previously thought of terminating the pregnancy
310 given the change in her partner's behaviour towards her following her disclosure of the pregnancy to him.

311 *“After I told him I was pregnant in April he started behaving strangely. He wasn't warm.”*

312 (Participant 13, 21-25 years old).

313

314 **1.2. Behavioural response of family following disclosure of** 315 **pregnancy**

316 Most participants reported that their families were shocked at the news of the pregnancy while
317 some reported that their families were highly disappointed with them as they had wished that the
318 young women could have focused on advancing their education or career. Despite this
319 circumstance, the relationships between the young women and their family members remained
320 stable and most were resident in the same households as their families and indicated feeling
321 supported by their families and also had a sense of closeness which contributed positively to their
322 pregnancy care and wellbeing. Most participants could confide and seek guidance from their
323 families and this played a significant role in their pregnancy care and wellbeing:

324 *“I thought that my parent was going to be angry or chase me away or something, but then my*
325 *parent sat down and spoke to me and told me to keep it, because my parent has never made*
326 *anyone do it, my parent is the first born so why does my parent have to judge me, life will*
327 *go on and we will be alright.”* (Participant 4, 16-20 years old).

328 “My parents asked me that they heard my grandparent telling them that I am pregnant and
329 I said yes I am pregnant. My parent said okay, there is nothing I can do since you are
330 already pregnant. I will not tell you to abort, when you are pregnant, you are pregnant. A
331 baby doesn’t have to be aborted and then my parents said that they will support me where
332 they are able to support me, and that I will understand, and I told my parent that I don’t
333 have a problem as long as you are going to support me, which is the only thing that I need,
334 and that was it.” (Participant 8, 21-25 years old).

335 “My relatives said whatever decision I take they will support me, whether I keep the baby or
336 not.” (Participant 16, 16-20 years old).

337
338 Contrary to these findings, the narrative of one participant showed that her relationship with her
339 family changed drastically following disclosure of her pregnancy, resulting in a dismantled
340 relationship and poor communication, and the participant experiencing negative emotions.

341 “My parent she was also disappointed, very disappointed I won’t lie but not as much as my
342 other parent, my parent was really like shattered, like yoh in so much disbelief, my parent
343 didn’t believe. It was hectic, hectic to a point where my parent cut me off financially, uh
344 nobody spoke to me until now that I’m 7... like last month when I was 7 months; so nobody
345 spoke to me basically for like 4 or 5 or 6... ja 3 months.” (Participant 17, 16-20 years old).

347 **1.3. Sense of emotional security**

348 The stories of the respondents indicated that they felt a sense of emotional security around their
349 pregnancies. An interpretation of their narratives is that this sense of security and positive

350 wellbeing stems from the fact that most participants have good social connections with family
351 members and sexual partners. The presence of families and partners in the participants' lives during
352 their pregnancy has led into increased feelings of comfort, joy, satisfaction and positive self-
353 awareness. This support and close relationships have also helped them to bond with their unborn
354 babies and to have increased pregnancy acceptance and positive wellbeing.

355
356 *“I’m happy, ja; like there’s nothing that I can think about because a baby is a gift and I had*
357 *to accept that it’s mine. I have a life inside of me I must take care of myself”* (Participant 7,
358 21-25 years old).

359
360 *“I feel great because like I’m carrying a fully-fledged human being, one that breathes and*
361 *is alive, ja”* (Participant 5, 16-20 years).

362 363 **2. Network Involvement**

364 **2.1. Emotional and instrumental support**

365 An exploration of the participants' narratives showed that both partners and families of the
366 pregnant young women are a key pillar in supporting the young women during their pregnancy
367 and helping them navigate through challenges associated with pregnancy. An interpretation of their
368 narratives shows that although the participants received financial support from their families and
369 partners, participants mostly received emotional support which contributed significantly to their
370 emotional wellbeing. The narratives also showed that some participants received most support

371 from their partners, some from their families and some had an equal balance of support from both
372 networks. In addition, partner and family engagements included provision of funds to meet
373 healthcare needs, food security, and provision of a conducive living environment. These narratives
374 suggest that partners and families demonstrated increased understanding and concern for maternal
375 care and wellbeing of the young women during their pregnancies, which contributed immensely to
376 positive pregnancy-related mental changes, being happy and accepting the pregnancy. This could
377 potentially contribute to engagement in healthy behaviours, which will positively contribute to a
378 successful delivery of the baby and positive post-partum care.

379 *“The support I get from my parent, it is better. Makes everything easier. My parent cooks*
380 *for me and makes sure I eat healthy.”* (Participant 10, 21-25 years old).

381
382 *“My partner supports me, he’s there emotionally, physically, financially he supports me with*
383 *everything that I need, he is there, we talk, his there, he is open, yeah. I am also under his*
384 *medical aid.”* (Participant 6, 21-25 years old).

385
386 *“He is just strong at being a very supportive partner. In terms of my education and job hunting*
387 *and he has been watching my diet since pregnancy. He is my dietician on that one,*
388 *emotional support he is there.”* (Participant 12, 21-25 years old).

389 Although Participant 12’s partner plays a key role in providing her with support in terms of her
390 furthering her education, looking for employment and ensuring that she participates in healthy

391 eating behaviours and providing for her financially, the participant indicated that her partner is not
392 emotionally invested in the “physical pregnancy”.

393 *“He doesn’t want to have those intimate experiences or moments with the baby. Because*
394 *sometimes okay, the first time I experienced the baby kicking, I asked him to come and feel*
395 *and he was just okay. He doesn’t ask much so I decided I’m no longer inviting him. He*
396 *does ask on when last I felt the baby kicking and I would tell him that I felt it earlier on.*
397 *He would then say I didn’t tell him but to me it would make no difference because he just*
398 *touches my stomach and say okay!”*. (Participant 12).

399 In addition to receiving both instrumental and emotional care from their family members and
400 sexual partners, two participants indicated also receiving support from the families of their sexual
401 partners. Partners’ families showed concern, acceptance, affection and warmth to the participants
402 and also provided them with emotional support which upon further interpretation suggests that
403 they felt a sense of responsibility and obligation towards the unborn child.

404 *“My partner, my family and partner’s family support me emotionally. When I have something*
405 *that bothers me from home or with my friends, I speak to him, and he is able to support me.*
406 *Makes me feel happy cause it is rare to find someone who is there with you and support*
407 *you, especially during tough times. Yes, I am able to talk to them.”* (Participant 1, 21-25
408 years old).

409
410 *“I think they are giving me love and they are trying to make me feel comfortable with the*
411 *pregnancy, because at first I was like no, my age and a second child, I won’t be able to,*
412 *and then my parent, my partner’s parent, they are there for me, that it’s something that*

413 *happens, that you want to study further, it's not something that will stop, like they give me,*
414 *they encourage me you see, we are there, we will stay with the child, you can carry on with*
415 *what you want to do and whatnot and whatnot, you see, so yeah.” (Participant 10, 21-25*
416 *years old).*

417 Despite these two narratives, an account of one participant showed that she has never had a
418 meaningful connection with the father in either of her two pregnancies, nor received any
419 instrumental help from him, his family or her own family. Such adversities have affected her
420 emotional wellbeing resulting in her feeling less happy about her pregnancy.

421 *“I've been having fights with the baby's father, so I have lost interest in the pregnancy.*
422 *Another thing is the lack of support from his family and mine. I sometimes feel depressed*
423 *like sad, I lost hope and I even regret why I fell pregnant.” (Participant 11, 21-25 years*
424 *old).*

426 **2.2. Information support**

427 The majority of the participants reported receiving peer support through friends who provided
428 support to the participants through sharing knowledge based on their own previous experiences,
429 emotional support, social interaction or practical help and information on pregnancy care and
430 pregnancy education from trial staff (details about intervention and control arms removed from
431 quotes to protect blinding). An interpretation of the narratives brings forth the argument that the
432 information support that the young women have received from the trial and health services has

433 contributed greatly to them having positive feelings about their pregnancies, feeling less isolated
434 and having improved emotional wellbeing; this may subsequently lead to increased parenting
435 capabilities.

436 *“I got most of the information from [the trial]. That is the one that made me understand most*
437 *about the baby. That when the baby gets to certain months, they can listen to sounds, they*
438 *can bond with you, the hair grows.”* (Participant 3, 16-20 years old).

439 *“The information that I have is about the growth of the baby, the change of the woman’s*
440 *baby, I got it from the clinic, obviously the card that I have, and then how the belly grows,*
441 *I have got a book from [the trial], we went through a lot of pages, it shows which month*
442 *the baby grows like this.”* (Participant 6, 21-25 years old).

443 *“I got support from [the trial] and the clinic. On how to raise the child and having to*
444 *breastfeed the baby up until six months for them to be healthy. Like how I am supposed to*
445 *eat, I must avoid stress most of the time.”* (Participant 14, 21-25 years old).

446
447 Other participants reported that they received information on pregnancy care from their friends.
448 These narratives showed that the emotional connection that they have formed with friends who
449 share similar experiences of pregnancy has helped them respond directly to their emotional needs,
450 which has contributed greatly to positive maternal care and wellbeing.

451 *“My friends fell pregnant when we were still at school, and so we talk about everything.*
452 *They are also open. I have open friends. So if we have challenges, we talk and help each*
453 *other. So most of the information I get from them.”* (Participant 1, 21-25 years old).

454 *“Some of the information I got it from my other friend. She has a baby so she has the*
455 *experience.”* (Participant 18, 26-30 years old).

456 Some participants also received information support from their families around pregnancy care,
457 through families imparting information on various traditional or cultural pregnancy practices that
458 the participants had to follow. The women’s narratives around this showed that the cultural
459 knowledge they possess around pregnancy has markedly influenced their pregnancy experiences
460 and related meaning-making. In particular, it has resulted in young women accepting their
461 pregnancies and protecting their health or pregnancies from a spiritual perspective.

462 *“The cultural practices that we follow at home and in my church during pregnancy is that*
463 *they tie you with a band on your waist to protect you, you drink water which they prayed*
464 *over, in case you come across evil and being pregnant, the baby catches a lot of things.”*
465 (Participant 1, 21-25 years old).

466 *“My parent gave me remedies to drink and waist braces. My parent said they protect the*
467 *child from evil spirits.”* (Participant 9, 16-20 years old).

468 *“My family took me to ‘someone’ (traditional healer) just so they can ‘strengthen my*
469 *pregnancy’. He said I must come with milk and eggs, ja and then he mixed them and he*
470 *said I must bathe with them, and then he said I must also bring Vaseline as well, and then*
471 *he mixed it I can’t remember what herbs he used, but then told me to lather my body with*
472 *it every night.”* (Participant 13, 21-25 years old).

473 *“There is a man that my parent took me to. He gave me water to drink. Water mixed with*
474 *some soil and a string. It was to tie the pregnancy because they suspected that I might*
475 *miscarry this one as well.”* (Participant 14, 21-25 years old)

476 *“My elders do tell me that I don’t have to show my stomach off all the time because people*
477 *out there can prevent me from delivering the baby and all that stuff; ja and also that I*
478 *should wash myself with ‘isiwasho’ (traditional medicine infused water). It’s to protect the*
479 *baby they say, ja and protect delivery.”* (Participant 16, 16-20 years old).

480 One participant reported that she received no information support from peers, health services,
481 members of her family or from her friends, but gathered the information herself through her own
482 learned experiences during her first pregnancy.

483 *“For me it happened naturally. It was just general knowledge, having to understand things*
484 *the way they should be. With my firstborn, I was breastfeeding him and I learned how to*
485 *take care of him.”* (Participant 11, 21-25 years old).

486

487 **Discussion**

488 The study’s objective was to explore the experiences of young females, in particular, receipt of
489 social support, and its effect on pregnancy care and wellbeing during the prenatal period, through
490 a phenomenological approach, in the context of Soweto, South Africa. The findings demonstrate
491 that support from members of their various relationship networks contributed greatly to the young
492 women’s pregnancy care and emotional wellbeing. Such support was found to be available to most

493 participants of the study, even though the support that they received either from their partner or
494 family, and the type of support that they received (instrumental, emotional and informational
495 support) somewhat varied. This contributes greatly to young mothers having increased acceptance
496 of their pregnancies and a greater sense of potential parental efficacy (36).

497
498 These findings address a critical gap in the literature, since the nature of social support has not
499 previously been explored from a qualitative perspective in South Africa. It is pivotal to acquire a
500 nuanced comprehension of these interactions and their role in maternal pregnancy care and
501 wellbeing since many young women face uncertainty about their emotional and cognitive readiness
502 in assuming a parental role (10). These cognitions and emotions do not exist in isolation but tend
503 to be influenced by one's interactions with various individuals namely friends, family members,
504 sexual partners and community members (10). Previous studies in the South African context have
505 mostly focused on the association between depressive symptomatology and social support in the
506 prenatal period (30, 73, 74) and social support among pregnant young women, including women
507 living with HIV (46, 75). Other quantitative research on social support in pregnancy has mostly
508 been conducted in mainly in non-African high-income settings (10) where social support has been
509 measured quantitatively and where measures of social support have been applied generically with
510 lack of relevance to a particular population (76).

511
512 The novelty of this study was therefore its qualitative exploration of the type of social and its source
513 perceived by young pregnant women in South Africa, and how this had an impact on their
514 pregnancy care and wellbeing. Exploring pregnant young women's social receipt within the
515 context of Soweto given that the area is largely a historically underprivileged high-density peri-

516 urban area in South Africa was vital, where young females are particularly afflicted by gender
517 inequality, impoverishment, low educational attainment, poor or lack of social capital, and and
518 economic disadvantages (77, 78). These social issues ultimately may expose them to gender-based
519 violence and early pregnancy, which have both become the norm in South Africa (77, 78).
520 Therefore, it was important to ground the narrative accounts of the young women within the
521 specific sociocultural context of Soweto, and within their experiences. The application of an
522 interpretive phenomenological approach has helped provide new insight as it has shed light on
523 realities and meaning-making around pregnancy and receipt of social support in this context.

524
525 It was further found in the study that partner and family behavioural responses to pregnancy
526 disclosure and type of social support that the young women received from these social networks,
527 played a significant role in their emotional wellbeing as well as in the young women taking an
528 initiative to focus on caring for their pregnancy and initiating antenatal care. This aligns with
529 evidence indicating the major influence that sexual partners and family members have in young
530 women's pregnancy care, and their physical and psychological wellbeing (37, 79-85). Also,
531 paternal or family support and stable relationships may mediate or combat distress on expectant
532 women which may reduce the risk of experiencing a poor birth outcome (86). This type of support
533 thus has the potential to increase their likelihood of experiencing positive birth outcomes and also
534 encourages young women to engage in positive pregnancy care behaviours.

535
536 Our findings on father support are congruent to other literature which has shown that partner
537 support, stability and dependability plays a key role in positive maternal behaviours and acceptance
538 of pregnancy (87). Moreover, an engaged partner who cares about the process of pregnancy

539 contributes positively to the psychological health and health behaviours of expectant females,
540 which subsequently results in positive pregnancy experiences (88). Thus it can be suggested that
541 young expectant females value the attachment that they have with their partners as they largely
542 deem these supportive networks as playing a key role in helping them to cope better with their
543 pregnancies. An unanticipated finding emerging from our findings was that most expectant females
544 reported receiving emotional and instrumental support from their sexual partners following
545 disclosure of their pregnancy, with partners accepting the pregnancies and having strengthened and
546 stable relationships with their partners.

547
548 Male partners were mostly cited as the main sources of social support with the type of support
549 received being of an emotional and instrumental nature. These findings seem contradictory to what
550 has been observed in previous literature, which indicates that unmarried fathers have increased
551 odds of being less involved during pregnancy than fathers who are in a marital union, thus having
552 no obligation towards providing social support to the mother during pregnancy (89, 90). Our
553 findings around partner support were also highly unanticipated given that intimate partner violence
554 is another social ill in South Africa which has partly contributed to young women being exposed
555 to early childbearing due to unequal power relations and the power of sexual coercion. This
556 compromises women's sexual health as women who are in relationships characterized by intimate
557 partner violence cannot employ their autonomy when it comes to the prevention of pregnancy and
558 contraceptive or condom use (90).

559
560 Expectant fathers have received limited attention in South African literature with respect to their
561 supportive role during pregnancy (91-93) with studies viewing fatherhood as only starting

562 postpartum (94, 95). Furthermore, South Africa is largely deemed as a country globally that is
563 characterized by high levels of father absenteeism (96-98) which can be partly traced back to the
564 apartheid regime, urbanization and labor migration, which had a strong impact on family life and
565 composition and changed the manner in which families functioned, with these changes being more
566 prominent in the roles of fathers, mothers and extended family members (99, 100). This lack of
567 participation in parenthood stems from the fact that most young fathers never knew their fathers
568 which has contributed greatly to their lack of guidance and experience on father roles and
569 responsibilities (100). Other constructs of fatherhood deem male emotional and nurturing forms of
570 support as “soft” behaviours (101) which suggests that fathers have to be emotionally distant (102).
571 In addition, non-involvement of young fathers can be attributed to the increase in poorly paid,
572 unprotected and insecure jobs and enduring rates of impoverishment and inequity in South Africa
573 that place men at a disadvantage of being able to provide adequate care to their families (103,
574 104). Of note, a previous study focusing on out of work and casual working young males in an
575 urban area of South Africa showed that some men have abandoned their paternal responsibilities
576 on the grounds that child support grants in the country have come to substitute men’s roles as
577 “providers” (105). Our findings regarding the role of partners’ support during pregnancy indicate
578 that further research is warranted to explore this role further.

579
580 Although some participants in this study reported receiving emotional and instrumental support
581 from their families, other participants reporting strained relationships with their families. A
582 possible explanation for this is that families punish young girls who fall pregnant through giving
583 them poor or no support which leads to challenges for young mothers to accept their pregnancies
584 and engage in positive maternal behaviours (106). This is because premarital childbearing has been

585 largely associated with social stigma and familial shame (107). Moreover, early childbearing
586 among young women in particular, from a socioeconomic standpoint, has been found to have
587 unfavorable results on the child, the young mother and extended family members (107-109). This
588 is because when a young woman is unmarried, the young mother and her family shoulder the
589 financial burden of childrearing (110).

590
591 The composition of household members and the number of members in the household have been
592 found to affect fertility behaviour significantly (111). South Africa has dynamic household living
593 arrangements, fewer people entering marital unions, and a rise in households in which adult
594 females are the sole or main income generators and decision-makers (112). In South Africa, the
595 role of the family has changed over time (100, 113) which has resulted in extensive changes in
596 living arrangements and familial responsibilities (114) and some families experiencing major
597 challenges in providing comprehensive care to their children, attributable to societal problems
598 associated with poverty, large family sizes, the HIV/AIDS pandemic and dismantling of the
599 nuclear family unit. These considerations need to be taken into account especially since these
600 factors can all serve as a set of varied and inter-related factors that can influence fertility behaviour
601 and outcomes of young women.

602
603 This current study found that other young women received support from both their sexual partners
604 and families while other participants either reported receiving support only from their partners or
605 only from their families. These findings suggest experiences of receipt of social support among
606 young women differ greatly, with the type and source of social support not being universal. For
607 instance, some young women experience pressure from their peers and forces to engage in sexual

608 activities in fear of their partners who threaten to end the relationship often resulting in unintended
609 pregnancies or termination (108, 115-117) while other young expectant females' experience of
610 pregnancy involves a denial of paternity (106). Conversely, other women have positive experiences
611 due to their partners accepting paternity and having an increased need to have a relationship with
612 their children, which is often a decision that is influenced by the partner's family
613 (67).

614
615 These experiences in turn affect young women's acceptance or non-acceptance of their pregnancies
616 given that the experience of childbearing among young women, its causes and consequences are
617 not uniform (106). Given that early childbearing among young women is a phenomenon that is
618 embedded within society (67) any changes that occur in society and any perceptions that members
619 of communities hold about early childbearing among young women, affect how young expectant
620 females experience pregnancy and motherhood (106). Also, complexities around communication
621 pertaining to young women's reproductive health increase their susceptibility to early childbearing
622 and affect how they experience pregnancy. It is thus pivotal to consider the significance of each
623 source of support and its well-being individually because pregnant young women are not a
624 homogenous group. They have a variety of demographic and familial characteristics, different
625 relations with their families and partners and the experiences and context in which they live may
626 differ which contributes greatly to engaging in positive maternal behaviours or lack thereof.

627
628 Since experiences of pregnancy are vastly different and complexities around family and partner
629 dynamics create different realities for these young women, social support needs to be relevant to
630 the different realities of young women. Focusing attention on pregnant women to identify those

631 who experience poor levels of social support along with the provision of community-based support
632 services in collaboration with partners and families, may help foster positive behavioural outcomes
633 with pregnant women taking an initiative to focus on caring for their pregnancy and initiating
634 antenatal care. Furthermore, interventions that urge young women to use personal networks are
635 needed. Health professionals can engage directly with partners and families of young women, by
636 providing information and training on how to support the young women whilst being sensitive to
637 the beliefs and cultural values of these sources of support. Health workers should also be
638 encouraged to mobilize the broader communities of these young women through mass-media
639 campaigns and discourses that promote the need for the supportive role of partners and families
640 and also empower young women to have agency and autonomy over the decisions they make on
641 their reproductive health.

642
643 The strength of this study is the application of the interpretive phenomenological approach, as it
644 helped the researchers to gain a nuanced understanding of participants' views and meaning-making
645 around the phenomenon under study. This provides in-depth insights into a particular context,
646 although transferability to other contexts should not be assumed, particularly since participants
647 were part of a trial. The study's limitation was that the support networks of the young women were
648 not included as study participants. These individuals could also provide their perspectives on how
649 they believe their provision of social support has had a major influence in the pregnancy care and
650 wellbeing of the young mothers.

654 **Conclusion:**

655 The existence of social support has a major influence on pregnancy care and wellbeing and a lack
656 thereof can pose significant risks on both maternal and child health. Focusing on social support
657 could help contribute to reducing maternal mortality rates and achieving reproductive health
658 accessibility universally. Pregnant women who receive sufficient social support from immediate
659 networks have increased potential to embrace and give attention to pregnancy-related changes.
660 This will, in turn, foster positive behavioural outcomes that encourage engaging in good pregnancy
661 care practices and acceptance of motherhood. The important role of maternal support during
662 pregnancy suggests that the wider community needs to be educated by policymakers and healthcare
663 providers about the importance of partner, family and peer support in order to minimize risks that
664 may affect maternal pregnancy care and wellbeing. Future research should be conducted that
665 explores the dynamics of social support within various family structures. Improving receipt of
666 social support by young mothers could enhance the promotion of physical and mental health of
667 mothers which would subsequently result in the engagement of healthy behaviours in the perinatal
668 period and positive birth outcomes.
