ABSTRACT

Background: Levodopa-induced dyskinesia (LID) is a common motor complication of levodopa therapy in patients with Parkinson's disease (PD). Doxycycline is a widely used and inexpensive tetracycline with anti-inflammatory properties. **Objective:** Evaluate the efficacy and safety of doxycycline in patients with PD and LID. **Methods:** This was an open-label, single-center, phase 2 proof-of-concept study in patients with PD with mild functional impact of dyskinesia, which used levodopa three times daily, in a movement disorders clinic in Brazil. Participants were treated with doxycycline 200 mg/day for 12 weeks, with evaluations in baseline, week 4, and week 12 of treatment. The primary outcome measure was the change from baseline in the Unified Dyskinesia Rating Scale (UDysRS) total score at week 12, evaluated by two blinded raters. Key secondary outcomes measures were OFF time and ON time with troublesome dyskinesia in the PD home diary. **Results:** Eight patients with PD were treated and evaluated. Doxycycline 200 mg/day reduced the UDysRS total score in week 12, compared with baseline (Friedman's $X^2 = 9.6$, $p = 0.008$). Further, doxycycline reduced the ON time with troublesome dyskinesia (Friedman's $X^2 = 10.8$, $p = 0.004$) without worsening parkinsonism. There were no severe adverse events, and dyspepsia was the commonest event. **Conclusions:** Doxycycline was effective in reducing LID and safe after a 12-week treatment. Further well-designed placebo-controlled clinical trials with a longer duration and a larger number of participants are needed.

Keywords: Parkinson disease, dyskinesias, doxycycline, neuroinflammation

INTRODUCTION

Parkinson's disease (PD) is the second most common neurodegenerative disease, affecting approximately 6.1 million people worldwide¹. Levodopa is the gold standard medical therapy for motor symptoms (bradykinesia, rigidity, tremor, gait disorders)². However, chronic treatment with levodopa causes the onset of levodopa-induced dyskinesia (LID), hyperkinetic involuntary movements temporally associated with the use of levodopa³.

The pathophysiology of LID is still not completely understood, but recent evidence has shown that neuroinflammation might be a leading cause of the onset of this motor complication. Animal models of dyskinesia have shown that the onset of abnormal involuntary movement in rats is associated with an increase in the density of astrocytes and activated microglia in the striatum, as well as a higher expression of proinflammatory mediators (GFAP, OX-42, TNF- α , iNOS) in neurons and glia of dyskinetic animals^{4,5}. In humans, there were high levels of a mediator of inflammation, the arachidonic acid, in the temporal cortex of postmortem brains of patients with PD who had developed motor complications (including LID), compared to healthy controls and patients with PD without motor complications⁶. Recent CSF analyses of patients with LID in PD revealed some neuroinflammatory abnormalities: a distinct metabolic profile strongly related to the dysregulation of lipid metabolism⁷ and high levels of nitrite and nitrate, which may be associated with the increased intrathecal production of nitric oxide by astrocytes and microglia⁸. These results suggest that a chronic pro-inflammatory state in the brain may be associated with LID onset⁹. Although it is unclear what drives this increased inflammation, targeting neuroinflammation might be a pharmacological strategy to limit this motor complication.

Until now, the only effective medication to reduce LID in PD without worsening parkinsonism is amantadine¹⁰, which may cause psychosis and livedo reticularis. Amantadine has been recently shown to possess anti-inflammatory effects¹¹. Many clinical trials tested the efficacy of different drugs in LID, with inconclusive results¹². As an alternative for this shortage of treatments for LID management, repurposing drugs with proven safety may be an efficient method to bring new therapies to patients¹³. Among the most investigated drugs for repurposing, antibiotics have been tested in neurodegenerative disease due to their several mechanisms of action through modulating signaling pathways¹⁴.

Doxycycline is an inexpensive second-generation semisynthetic tetracycline with easy penetration of the blood-brain barrier, reduced toxicity, longer half-lives, superior tissue fluid penetration¹⁵, with exceptional bioavailability¹⁶. Despite being commonly used as an antibiotic to treat infectious diseases, doxycycline is also prescribed as an anti-inflammatory drug in the management of acne vulgaris and rosacea. Indeed, the therapeutic rationale for targeting neuroinflammation is further supported by the observation of a reduced risk of PD in individuals using tetracyclines for rosacea treatment¹⁷. The treatment with doxycycline is associated with few adverse events, particularly gastrointestinal symptoms and skin reactions, even after long-term administration¹⁸. However, there are some concerns about its long-term treatment, such as antibiotic resistance and interference on gastrointestinal microbiota.

Doxycycline has an anti-inflammatory effect in the nervous system, based on inhibition of glial activation in the substantia nigra and the striatum and suppression of metalloproteinase

induction¹⁹. Also, doxycycline reduces the transcription of proinflammatory mediators suppressing the p38 MAPK and NF- κ B signaling pathways¹⁵, and restraining angiogenesis²⁰.

Previously, doxycycline reduced the dopaminergic cell loss in rodent PD models¹⁹, and inhibited microglia activation in an in vitro model of neuroinflammation¹⁵. Regarding LID, a recent study showed that acute and chronic intraperitoneal administration of doxycycline reduced the onset of dyskinesias in a rat model of LID. Furthermore, doxycycline reduced the expression of molecular markers of LID (FosB, COX-2, GFAP, OX-42) in the striatum of rats that developed dyskinesias. A derivative of doxycycline without antibiotic properties, COL-3, also reduced the onset of dyskinesias²¹.

Considering the low cost and good safety of doxycycline and its modulating effect on neuroinflammatory mechanisms, it may represent a new therapy for LID management. Thus, we conducted an open-label, proof-of-concept phase 2 clinical trial to analyze the effects of doxycycline in LID in patients with PD.

MATERIALS AND METHODS

Study design and participants

We performed an open-label, single-center, phase 2 proof-of-concept study to assess the efficacy and safety of doxycycline for 12 weeks in patients with PD and LID. Participants were recruited

in the Movement Disorders Unit of Ribeirão Preto Medical School, Brazil, between October 2019 and May 2021. The study was conducted following the Declaration of Helsinki and Good Clinical Practice Guidelines and was approved by the Ribeirão Preto Medical School Ethics Committee (number 3.055.052). All patients provided written informed consent.

As inclusion criteria, we selected: patients aged 18 years or older; diagnosis of PD according to the UK Parkinson's Disease Society Brain Bank clinical diagnostic criteria; at least a mild functional impact of dyskinesia in the Movement Disorder Society - Unified Parkinson's Disease Rating Scale (MDS-UPDRS)²² Part IV (item 4.2 score > 1) at screening and baseline; use of levodopa at least three times daily; antiparkinsonian medications doses unchanged for at least four weeks before screening and during study participation.

As exclusion criteria, we excluded: atypical or secondary parkinsonisms; treatment of any experimental drug or intervention within 90 days before screening; moderate or severe psychotic symptoms (MDS-UPDRS Part I, item 1.2 score > 2); dementia according to MDS diagnostic criteria²³; severe systemic conditions (infections, malignant neoplasms, chronic kidney or liver diseases); pregnancy or lactation; history of hypersensitivity or allergic reaction to tetracyclines; no clinical dyskinesic movements at baseline.

Treatment

The study consisted of a 2-week titration phase and a 10-week maintenance phase. The dose of doxycycline 200 mg/day was chosen based on an optimized plasmatic concentration and usual

dose in long-term treatments²⁴. Initially, patients self-administered one capsule of doxycycline 100 mg after breakfast once a day for two weeks; after two weeks of treatment, patients were evaluated by investigators in person; if investigators and patients reported no improvement in dyskinesic movements, the dose was increased to 100 mg b.i.d in week 3. After, patients were maintained on a constant dose of doxycycline until the end of week 12, when the drug was withdrawn. All antiparkinsonian medications were maintained unchanged until the end of the study.

Assessments and outcome measures

Patients were evaluated at baseline and weeks 4 and 12 by a movement disorders specialist. Before the baseline visit, patients were trained in filling out the PD home diary, and diary concordance testing between patients and investigators was performed. Patients completed PD home diaries to assess their motor status every half hour for 24 hours for three consecutive days before baseline visit and before weeks 4 and 12 visits, and we calculated the three-day average from home diaries. Motor status was assessed as asleep, OFF time, ON time without dyskinesia, ON time with non-troublesome dyskinesia, and ON time with troublesome dyskinesia²⁵. For analyses, the sum of ON time without dyskinesia with ON time with non-troublesome dyskinesia was called “ON time without troublesome dyskinesia.” At each visit, patients were instructed not to take their regular doses of antiparkinsonian drugs 12 hours before the evaluation and to be on an empty stomach.

As the first step of the baseline visit, patients were evaluated with the MDS-UPDRS in OFF state. After, patients ingested their regular dose of levodopa increased by 50% and were evaluated with the MDS-UPDRS Part III and the Unified Dyskinesia Rating Scale (UDysRS)²⁶ in ON state; ON state evaluations were filmed for posterior assessment of two blinded investigators. Also, clinical and demographic data were recorded, and the completed PD home diary was reviewed. The same evaluations were performed at LID weeks 4 and 12, including the Clinical Global Impression of Change (CGIC) scale²⁷ for patients and investigators regarding the change of intensity in dyskinesias compared to the baseline.

The primary outcome measure was the change from baseline in the UDysRS total score at week 12. Key secondary outcomes measures were OFF time and ON time with troublesome dyskinesia in the PD home diary. Other secondary outcomes measures included changes between baseline and week 12 visit in MDS-UPDRS Parts III and IV and total scores (ON state), ON time without troublesome dyskinesia in the PD home diary, and patient- and investigator-related CGIC.

Statistical analysis

We performed a modified intention-to-treat analysis. Changes from baseline to weeks 4 and 12 in the outcomes (UDysRS, MDS-UPDRS, time measures from PD home diary) were assessed using the Friedman test to compare multiple repeated measures, and the Wilcoxon signed-rank test was used to compare baseline and week 12. Effect sizes were calculated based on the Wilcoxon signed-rank Z value by the square root of the number of related pairs. Missing data were imputed according to the last observation carried forward method.

RESULTS

Study population and baseline characteristics

A total of fifteen patients were screened, and eight patients met the inclusion criteria and were enrolled in the study (Figure 1). The most common reason for failure in enrollment was that patients (n = 5) had difficulties understanding the PD home diary filling procedures. Baseline demographics are provided in Table 1. The patients were predominantly women (6 women and two men), had long PD and LID duration (median 17 and 10 years, respectively), and used high doses of antiparkinsonian drugs (median 1162 mg/day). Four patients had moderate scores, and the other four had severe scores in time spent with dyskinesias on item 4.1 of the MDS-UDPRS. Two patients had mild scores, four had moderate scores, and the other two had severe scores in the functional impact of dyskinesias on item 4.2 of the MDS-UDPRS.

All patients received a daily dose of doxycycline 100 mg initially, and after two weeks, the daily dose was increased to 200 mg. All patients completed the treatment for 12 weeks, and all patients were evaluated at the baseline, at week 4 and week 12. One patient had issues reporting the PD home diary, and these data were excluded from the analysis.

Outcomes

The primary efficacy analysis showed that the treatment with doxycycline was associated with a reduction in UDysRS total score until week 12 (Friedman's $X^2 = 9.6$, $p = 0.008$; week 12 compared to baseline, Wilcoxon $Z = -2.521$, $p = 0.008$; effect size = 0.89) (Figure 2, Table 2). There was a reduction in the historical subscore of the UDysRS until week 12 (Friedman's $X^2 = 12.6$, $p = 0.002$; week 12 compared to baseline, Wilcoxon $Z = -2.524$, $p = 0.008$), but not in the objective subscore (Friedman's $X^2 = 1.31$, $p = 0.51$).

PD home diary measurements showed significant clinical improvements after treatment with doxycycline through 12 weeks: reduction of ON time with troublesome dyskinesias (Friedman's $X^2 = 10.8$, $p = 0.004$; week 12 compared to baseline, Wilcoxon $Z = -2.36$, $p = 0.016$; effect size = 0.89) and increase of ON time without troublesome dyskinesias (Friedman's $X^2 = 6.74$, $p = 0.03$; week 12 compared to baseline, Wilcoxon $Z = -1.69$, $p = 0.1$) (Figure 3, Table 2).

There was no worsening of parkinsonism after 12 weeks of treatment with doxycycline measured by total score and Part III of the MDS-UPDRS in ON state (Table 2). There was no modification of the MDS-UPDRS Part IV after treatment, but there were significant reductions in scores of time spent with dyskinesias (item 4.1, Friedman's $X^2 = 6.61$, $p = 0.03$; week 12 compared to baseline, Wilcoxon $Z = -2.07$, $p = 0.063$) and functional impact of dyskinesias (item 4.2, Friedman's $X^2 = 11.5$, $p = 0.003$; week 12 compared to baseline, Wilcoxon $Z = -2.56$, $p = 0.008$).

The CGIC scale results showed an overall agreement between impressions from investigators and patients, with all patients assessed as improved by investigators after treatment with

doxycycline at week 12, and seven of eight patients self-reported themselves as improved (87.5%).

Safety

Overall, six patients (75%) reported at least one adverse event, one (12.5%) patient had a moderate adverse event, and no patient had an adverse event that led to discontinuation of the therapy or serious adverse events. Most adverse events were grade 1 or 2 according to the Common Terminology Criteria for Adverse Event (version 5.0). Most of these adverse events were drug-related, and dyspepsia (n = 4; all grade 1) and abdominal pain (n = 2; one grade 1 and one grade 2) were the most common events. Nausea (n = 1), headache (n = 1) and somnolence (n = 1) were also described.

DISCUSSION

Doxycycline 200 mg daily for 12 weeks reduced LID frequency, severity, and functional impact in patients with PD using levodopa, as assessed by UDysRS, PD home diary, MDS-UPDRS, and CGIC. Also, doxycycline increased ON time without troublesome dyskinesias, without worsening motor and non-motor symptoms. From baseline, the UDysRS total score was 11 points lower and ON time without troublesome dyskinesias was 2.77 hours shorter in week 12. In the baseline, all patients with PD had LID during at least 50% of their waking day (MDS-UPDRS item 4.1 scores 3 and 4), and 75% of patients had LID, which impeded their activities

(MDS-UDPRS item 4.2 scores 3 and 4); after doxycycline (week 12), only 50% of patients had LID during at least 50% of waking day, and no patient had LID which impeded activities.

The treatment with doxycycline 200 mg daily showed no serious adverse events. Dyspepsia, the most frequently observed adverse event, was mostly mild and did not cause discontinuation of the drug.

UDysRS total score has been suggested as the preferred primary outcome for clinical trials on LID²⁸. Minimal clinically important difference (MCID) in LID has been explored recently. For UDysRS, there are established MCID for the historic subscores (Part 1 - ON dyskinesia, -2.1 points; Part 2 - OFF dyskinesia, -1.8 points)²⁹ and the impairment subscore of the scale (Part 3, -2.32 points)³⁰. Our study showed a clinically important reduction of 10.5 points for the historic subscore Part 1 in week 12, but without significant reductions in Parts 2 and 3 of the UDysRS.

For comparison, the 274 mg extended-release oral formulation of amantadine (ADS-5102) once daily at bedtime was approved by the FDA in 2017 for the treatment of LID after positive results from two phase 3 randomized and controlled trials (EASE LID³¹ and EASE LID 3³²). These studies showed a reduction of -15.9³¹ and -20.7 points³² in the UDysRS total score after ADS-5102 in week 12, as well as our doxycycline trial indicated a reduction of 11 points in the UDysRS in week 12. Also, ON time without troublesome dyskinesias increased in 3.6³¹ and 4 hours³² after ADS-5102 in week 12, and doxycycline increased the ON time without troublesome dyskinesias by 2.77 hours. A recent pooled analysis of these two studies calculated the magnitude of reduction of ON time with dyskinesias after ADS-5102 as a Cohen d effect size of

0.49³³. For comparison, our effect size for reduction of ON time with troublesome dyskinesias after doxycycline was 0.83.

Another antibiotic has shown antidyskinetic properties: ceftriaxone slowed the development of abnormal involuntary movements but did not change previously established LID³⁴, acting through the expression of glutamate transporter 1. Furthermore, doxycycline may have an additional positive effect in PD: inhibition of alpha-synuclein aggregation. Doxycycline inhibits the formation of toxic misfolded forms of alpha-synuclein oligomers through protein aggregation and blocks the seeding capacity of preformed aggregates in an in vitro and in vivo model³⁵. Recently, another study in vivo confirmed these findings³⁶.

A recent clinical trial showed that intestinal decontamination with colon enemas and the luminal antibiotic rifaximin reduced LID in patients with advanced PD³⁷. The authors suggested that the therapy modified gut dysbiosis, common in PD³⁸. Gut dysbiosis causes a systemic pro-inflammatory status that increases the brain-blood barrier permeability, promoting neuroinflammation together with bacterial products from the gut microbiota³⁹. Doxycycline may also be effective in LID by reducing neuroinflammation mediated by gut dysbiosis.

As limitations, our study was not randomized and controlled, as well as the small size may have underpowered the results. Also, the short duration of treatment (12 weeks) may not be adequate to measure efficacy and safety for oral doxycycline 200 mg daily in LID. An additional group for doxycycline in a smaller daily dose could be included in further studies, considering that its antidyskinetic effect may not be associated with an antibiotic dose. The reduction of LID in rats

after treatment with sub-antibiotic doses of doxycycline and with its derivative without antibiotic effect COL-3 might be used to reduce the risk of adverse events related to long-term therapy²¹.

In conclusion, this proof-of-concept clinical trial first revealed that doxycycline could directly modulate LID in accordance with previous preclinical studies. Therefore, further well-designed placebo-controlled clinical trials with a longer duration and a larger number of participants would be the next logical step in this field.

Table 1 Baseline clinical and epidemiological data of the eight patients.

Male sex, % (n)	25 (2)
Age at the time of evaluation (years)	57.5 (53-65)
Age at onset of PD (years)	41 (39-48)
Mini-Mental State Examination	27 (25-29)
Disease duration (years)	17 (8-21)
LID duration (years)	10 (5-12)
Levodopa daily dose (mg/day)	850 (724-1072)
Levodopa equivalent daily dose (mg/day)	1162 (975-1701)
Concomitant medication use	
Use of dopaminergic agonists, % (n)	50 (4)
Use of amantadine, % (n)	75 (6)
Use of MAO inhibitors, % (n)	0 (0)
MDS-UPDRS	
Part I	11 (6-25)
Part II	26 (15-35)
Part III (ON state)	32 (27-38)
Part III (OFF state)	53 (34-61)

Part IV	10 (8-12)
Total score (ON state)	77.5 (60-109)
Hoehn & Yahr (ON state)	2 (2-3)
PD home diary	
ON time with troublesome dyskinesia (hours)	4.17 (2-7)
ON time without troublesome dyskinesia (hours)	7.34 (4-10)
OFF time (hours)	4.5 (1-5)
Participants with OFF time, % (n)	100 (8)
UDysRS	
Historical subscore	31 (28-33)
Objective subscore	36 (31-49)
Total score	47.75 (46-59)

Values are median (interquartile range) or % (n). Abbreviations: COMT, catechol-O-methyltransferase; LID, Levodopa-induced dyskinesias; MAO, monoamine oxidase; MDS-UPDRS, Movement Disorder Society–Unified Parkinson’s Disease Rating Scale; PD, Parkinson’s disease; UDysRS, Unified Dyskinesia Rating Scale.

Table 2 Efficacy results at the end of the treatment with doxycycline in the modified intention-to-treat population.

General characteristics	Baseline	Week 4	Week 12	P-value
Primary outcome				
UDysRS Total score	47 (46-59)	44 (37-51)	36 (32-48)	0.008
Key secondary outcome				
ON time with troublesome dyskinesia (hours)	4.1 (2-7)	1 (0.3-2)	1.33 (0.5-2)	0.04
OFF time (hours)	4.5 (1-5)	3.5 (0.6-5)	5 (2-5)	0.36
Other secondary outcomes				
MDS-UPDRS Part III (ON state)	32 (27-38)	30 (24-37)	30 (24-39)	0.65
MDS-UPDRS Part IV	10 (8-12)	9.5 (8-11)	8 (7-9)	0.14
MDS-UPDRS Part IV, item 4.1	3.5 (3-4)	3 (2-3)	2.5 (2-3)	0.01
MDS-UPDRS Part IV, item 4.2	3 (2-4)	2 (2-2)	1 (1-2)	0.002

MDS-UPDRS Total score (ON state)	77 (60-109)	70 (50-88)	70 (53-88)	0.19
ON time without troublesome dyskinesia (hours)	7.3 (4-10)	9.6 (7-13)	8.1 (8-13)	0.03

Values are median (interquartile range). Abbreviations: MDS-UPDRS, Movement Disorder Society–Unified Parkinson’s Disease Rating Scale; UDysRS, Unified Dyskinesia Rating Scale.

Figure Legends:

Figure 1 Fluxogram of the study. Abbreviations: CGIC, Clinical Global Impression of Change; PD, Parkinson's disease; UDysRS, Unified Dyskinesia Rating Scale.

Figure 2 Change in the UDysRS total score over time (modified intention-to-treat population). Abbreviations: UDysRS, Unified Dyskinesia Rating Scale.

Figure 3 Change in the average time in different motor status according to the PD home diary over time (modified intention-to-treat population). Values are median (interquartile range).

Enrollment

Assessed for eligibility (n = 15)

Excluded (n = 7)

- Not meeting inclusion criteria (n = 2)
- Issues on filling PD home diary (n = 5)

Allocation

Allocated to intervention (n = 8)

Follow-Up

Completed 12 weeks of
treatment (n = 8)

1 patient was not evaluated in week 12
1 patient did not complete UDysRS, CGIC
and PD home diary evaluation in week 12

Analysis

Included for modified intention-
to-treat analysis (n = 8)

Average time in different motor status in 24 hours
