**Introduction:** Experiences of discrimination and bias in health care contribute to health disparities for LGBTQ+ and other minority populations. To avoid discrimination, many LGBTQ+ people go to great lengths to find healthcare providers who they trust and are knowledgeable about their health needs. This study examines whether access to an LGBTQ+ affirming provider may improve health outcomes for LGBTQ+ populations across a range of preventive health and chronic disease management outcomes.

**Methods:** This cross-sectional study uses Poisson regression models to examine original survey data (n=1,120) from Wave 1 of the Vanderbilt University Social Networks, Aging, and Policy Study (VUSNAPS), a panel study examining older (50□76 years) LGBTQ+ adults' health and aging, collected between April 2020 and September 2021.

**Results:** Overall, access to an LGBTQ+ affirming provider is associated with greater uptake of preventive health screenings and improved management of mental health conditions among older LGBTQ+ adults. Compared to participants reporting a usual source of care that is not affirming, participants with an LGBTQ+ affirming provider are more likely to have ever and recently received several types of preventive care, including past year provider visit, flu shot, colorectal cancer screening, and HIV test. Access to an LGBTQ+ affirming provider is also associated with better management of mental health conditions.

**Conclusions:** Inclusive care is essential for reducing health disparities among LGBTQ+ populations. Health systems can reduce disparities by expanding education opportunities for providers regarding LGBTQ+ medicine, adopting nondiscrimination policies for LGBTQ+ patients and employees, and ensuring LGBTQ+ care is included in health insurance coverage.

## INTRODUCTION

Up to one-third of lesbian, gay, bisexual, transgender, and queer (LGBTQ+) Americans avoid seeing a doctor for fear of discrimination.[1,2] Others go to great lengths to find healthcare providers who they trust, will affirm their identities, and are knowledgeable about their health needs.[3-6] This study examines the association of access to LGBTQ+ affirming health care with lifetime and timely receipt of preventive health screenings and chronic diseases management outcomes among older LGBTQ+ adults.

While there are no uniform standards for assessing what constitutes LGBTQ+ affirming clinical care, previous work suggests that there are 2 key domains: (1) *clinical competence*, such as understanding specific health needs among LGBTQ+ individuals, and (2) *cultural competence*, which includes respectful communication and interaction with LGBTQ+ individuals.[7-11] Researchers operationalize LGBTQ+ affirming care at multiple levels (Figure 1), including at the interpersonal level (e.g., during the patient encounter), the institutional level (e.g., the presence of nondiscrimination policies), and the structural level (e.g., laws or rules regulating the provision of gender affirming care). Most research focuses on interpersonal barriers to receiving affirming care, such as disclosure of sexual orientation or gender identity to providers.[12-19] LGBTQ patients may also experience barriers to accessing affirming care, including lack of insurance or distance to an LGBTQ+ affirming provider.[5,6]

There are several potential benefits of receiving care from an LGBTQ+ affirming provider. Broadly, affirming care environments may improve health outcomes for LGBTQ+ patients by promoting engagement and retention in care, more timely preventive screenings, provider trust,

uptake of provider recommendations, earlier diagnoses, and more open conversations about needs and concerns. As evidence of this, HIV-negative gay and bisexual men with LGBTQ+ affirming providers are more likely to have ever tested for HIV and to be aware of current HIV prevention strategies such as *Undetectable = Untransmitable*.[20] At the institutional level, patients report higher satisfaction when health systems are LGBTQ+ affirming regardless of sexual orientation or gender identity.[21] Affirming care practices and explicit nondiscrimination policies may also allow for greater involvement of partners and caregivers in contexts like cancer care, where patients have concerns about disclosing their LGBTQ identity and bringing their partner to appointments.[22–24]

Conversely, when patients do not feel comfortable disclosing or are not asked[19] about their sexual orientation, gender identity, or sexual behavior, this can lead to inattention to health needs and missed diagnostic screenings.[17,18,25–27] Gay and bisexual men who do not disclose their sexual orientation to their primary provider are less likely to receive HIV and other STI tests and hepatitis vaccinations.[12,28–30] The lack of affirming care options for sexual minorities and transgender people can also lead to healthcare fragmentation, where individuals seek care outside of primary care contexts because of gaps in provider knowledge, greater comfort with community providers, or expectations of discrimination.[31,32] Finally, experiences of disrespect toward a patient's partner are not uncommon in healthcare settings[33] and may decrease partner involvement in care decisions.[22–24,34]

This study focuses on older LGBTQ+ adults aged 50 to 76 years, a cohort that has experienced substantial individual, institutional, and structural discrimination throughout their lives.

Consistent with accumulated exposure to minority stressors across the life course, health disparities by sexual orientation and gender identity are especially pronounced at older ages.[35–39] Experiences of discrimination, stigma, and harassment within healthcare settings reinforce and exacerbate health disparities.[27,40] By focusing on older adults aged 50 to 76 years, a group that is understudied despite high rates of unmet medical needs,[41] this study is able to assess both lifetime and timely uptake of many preventive cancer screenings that only are recommended later in life.

Additionally, by focusing on the U.S. South, where an estimated 35% of LGBTQ+ adults in the U.S. live, this study offers insight into how expanding access to LGBTQ+ affirming care might intervene in the poorer health trajectories of LGBTQ people in Southern states,[42] even as many of these states pursue criminalization of gender affirming care and make allowances for providers to deny care on the basis of religious belief to LGBTQ+ patients.[43]

## METHODS

### Study Sample

This study uses survey data from Wave 1 of the Vanderbilt University Social Networks, Aging, and Policy Study (VUSNAPS; n=1,256), a panel study examining older LGBTQ+ adults' health and aging, collected between April 2020 and September 2021. Respondents included LGBTQ+ adults aged 50 to 76 years residing in Alabama, Georgia, North Carolina, and Tennessee recruited via community outreach at LGBTQ+ and senior organizations, events, and paid targeted online ads on social media platforms. These states were selected because they reflect the diversity of population and policy relevant to LGBTQ+ populations in the U.S. South. The

VUSNAPS Wave 1 sample generally reflects the demographic characteristics of the LGBTQ population aged 50 to 76 years age for sample states and the U.S. South as measured by the U.S. Census Household Pulse Survey (HPS), Phase 3.2, weeks 34□39 (Appendix Table 1).[44] Compared to weighted HPS estimates of demographic characteristics of LGBTQ people in the U.S. South, VUSNAPS participants are more educated (71% college degree or higher vs 32% in HPS), less likely to identify as bisexual (11% vs 26%), and less likely to identify as Latino/Hispanic (1% vs 17%). This study was approved by the Vanderbilt University IRB.

Analyses were restricted to LGBTQ+ individuals with a usual source of care to avoid comparing LGBTQ+ affirming care to those without care and to estimate the marginal benefit of having an LGBTQ+ affirming provider versus standard care. The analytic sample included 1,120 respondents, excluding 105 participants who reported the emergency room as their usual source of care and 31 respondents who were missing covariate information on education and/or household income.

**Measures**

Respondents were asked "Do you have an LGBT-affirming health care provider?" with response options: "Yes, they are my primary health care provider; Yes, I see them in addition to another health care provider; No, I don't need or want an LGBT-affirming health care provider; No, I cannot find an LGBT-affirming health care provider in my area; I don't know; and No answer." Respondents who reported "Yes" were coded as having access to an LGBTQ+ affirming health care provider. All others were coded as no.

Preventive health outcomes included receipt of timely and lifetime preventive care. Respondents were asked if they had "seen a doctor or health care provider" in the past year. Receipt of lifetime preventive care was assessed by asking, "Have you ever had any of the following preventive care screenings or tests?" including flu shot, breast cancer screening or mammogram (participants assigned female at birth [AFAB]), Pap test (participants AFAB), colorectal cancer screening or colonoscopy, and HIV test (participants who are HIV negative and identify as cisgender male, transgender male, transgender female, or gender non-conforming). If respondents indicated ever having 1 or more of these tests, timely receipt was assessed by asking, "Have you had any of the following tests or screenings in the last 3 years?"). Although screening recommendations vary, the U.S. Centers for Disease Control and Prevention and the U.S. Preventive Services Task Force recommend mammogram screening, cervical cancer screening, and HIV testing at least every 3 years for most adults in this sample.[45] Colorectal cancer screening is recommended for all adults beginning at age 50 years, and then every 5 to 10 years depending on screening mode and risk factors. Given the age range of the sample, only lifetime receipt of colorectal cancer screening is examined.

Chronic disease management was based on measurement of 5 common conditions with elevated prevalence among LGBTQ+ populations: high blood pressure, diabetes, any heart condition, any respiratory condition, any mental health condition.[46,47] Conditional on having a specific health condition, respondents were asked: "Is your condition [high blood pressure, diabetes, heart condition, respiratory condition, mental health condition] pretty much under control (1) or is it still a problem (0)?").

**Statistical Analysis**

All analyses were conducted using Stata v17. Chi-square and unadjusted Poisson regression were used to test bivariate differences in the distributions of responses. For binary outcome variables, adjusted prevalence ratios using modified Poisson models with robust error variance were estimated.[48,49] Adjusted analyses controlled for factors identified in prior research predicting LGBTQ healthcare use and access,[11] including: age, gender identity, sexual orientation, race/ethnicity, education, income, health insurance status, state of residence, whether the respondent had seen a doctor or healthcare provider in the past year (except where outcome), and the presence of any chronic condition (preventive outcomes only).

## RESULTS

About two-thirds (63%) of respondents had an LGBTQ+ affirming provider. Among the remaining one-third of respondents (N=412), a majority (64.3%) indicated that they did not know if their provider was affirming, 17.5% indicated that they did not need or want and LGBTQ+ affirming provider, and 13.1% could not find one. All respondents reported a usual source of care despite not having an LGBTQ+ affirming provider.

Table 1 presents demographic characteristics of the sample by access to an affirming provider. There were significant differences in the distribution of access to an LGBTQ+ affirming care provider across several demographic characteristics. Most notably, respondents with an LGBTQ+ affirming provider were more likely to: be cisgender men ($p<0.05$) or transgender women ($p<0.05$) than cisgender women; be gay than bisexual ($p=0.001$); have completed a graduate or professional degree than have less than a college degree ($p=0.05$); be living in North Carolina compared with Alabama ($p=0.05$); and be living with HIV ($p<0.001$).

Table 2 presents adjusted prevalence ratios for the associations among having an LGBTQ+ affirming care provider and preventive care and chronic disease management outcomes. Compared to respondents receiving standard care, respondents with an LGBTQ+ affirming provider were more likely to have ever and recently received several types of preventive care. Individuals with an LGBTQ+ affirming provider were 3.8% (95% CI=1.1%, 6.7%, $p<0.01$) more likely to have seen a doctor in the past year, 7.0% (95% CI=0.1%, 14.3%, $p<0.05$) more likely to have ever had a colorectal cancer screening, 6.0% (95% CI=1.2%, 11.1%, $p<0.01$) more likely to have ever had a flu shot, and, 7.8% (95% CI=2.2%, 13.7%, $p<0.01$) more likely to have had a flu shot in the last 3 years. Among those most at risk of HIV, respondents with an affirming provider were 13.9% (95% CI=3.8%, 24.9%, $p<0.01$) more likely to have ever had an HIV test, and 32.7% (95% CI=7.2%, 64.4%, $p<0.01$) more likely to have an HIV test in the last 3 years. There were no differences in timely or lifetime receipt of Pap test and mammogram screenings among participants assigned female at birth. Figure 2 plots adjusted prevalence ratios for all preventive care and chronic disease management outcomes.

LGBTQ+ individuals with a mental health condition were 10.8% (95% CI= ☐1.4%, 24.4%, $p<0.10$) more likely to report their condition "under control" when they had an affirming provider versus standard care. There were no significant differences by provider type in the likelihood that respondents reported other health conditions as "under control."

**DISCUSSION**

Access to an LGBTQ+ affirming provider varied across demographic characteristics and was associated with receipt of several preventive care outcomes and better patient-reported management of mental health conditions. Respondents who had LGBTQ+ affirming healthcare provider were more likely to have had a doctor's visit in the past year, to have ever had a flu shot, and to have ever had a colorectal cancer screening compared to LGBTQ+ adults receiving standard care.

LGBTQ+ adults with a mental health condition were also more likely to report that their mental health condition was under control when they had an affirming provider. This finding is consistent with other work showing the benefits of accessing gender affirming care for mental health among transgender young people[50–53] and adults.[54]

Notably, those most at risk of HIV were more likely to have ever had an HIV test and more likely to have had an HIV test in the last 3 years when they had an LGBTQ+ affirming provider. More than half of new HIV infections in the U.S. occur in the South, and people living with HIV are more than 3 times more likely to die from the disease compared to the rest of the country.[56] Links between affirming care and HIV prevention outcomes in this and other studies[20] help us better understand the poorer HIV trajectories of the U.S. South, where LGBTQ patients face a dearth of LGBTQ affirming providers[55] and are more likely to live in states with laws that deny or limit health care for sexual and gender minorities.[43]

Respondents with an affirming care provider also had higher rates of lifetime receipt of colorectal cancer screening, most of which are conducted via colonoscopy.[57] While there may be

several aspects of affirming care that are relevant to this outcome, related work suggests that cultural competency and trust are especially important for acceptability and uptake of invasive procedures like colonoscopy among minority populations.[58]

Although sexual minority women are less likely to be offered a Pap test than heterosexual women,[59] there were no associations between having an LGBTQ+ affirming provider and lifetime or timely receipt of Pap test or mammogram screenings among LGBTQ+ individuals AFAB. This is likely explained by several factors. The study does not include information on current anatomy; thus, analyses may include individuals for whom these screenings would be inappropriate. Patient care and research with transgender and gender diverse populations should adopt anatomical inventories in electronic health records and study measures to improve accuracy and patient-centeredness of care.[60] Additionally, Pap tests and mammograms have higher rates of completion compared with other screenings,[57] longer lifetime risk exposure (Pap test), and higher acceptability compared to HIV tests or colorectal cancer screenings.[61–64]

There are several behaviors that may promote higher uptake of preventive care and better mental health management among individuals with an affirming provider, including the use of visual cues, such as a rainbow pin,[65] or communicating to cisgender gay and bisexual men that they are at elevated risk for developing colorectal cancer.[66] LGBTQ+ affirming providers may also support patient uptake of invasive procedures by using gender-neutral language when asking patients whether they have a spouse or partner who can provide transportation and support afterward. By engaging in these varied practices, LGBTQ+ affirming clinicians and institutions may allow for earlier diagnoses, more open conversations about patient concerns, and greater

patient uptake of provider recommendations. Additionally, among populations where many are hesitant or lack trust in their healthcare providers,[35,67] retention in care, measured here as having had a recent visit to a usual source of care, is a major achievement.

Health systems should prioritize LGBTQ+ inclusive best practices to achieve health equity for LGBTQ+ populations. Best practices identified by the American Medical Association include the visible display of information and images that reflect and center LGBTQ identities and health concerns, and the collection of sexual orientation and gender identity on patient intake forms.[68,69] In addition, institutions should adopt higher level policy statements on nondiscrimination of LGBTQ patients and employees; provide gender-neutral restroom facilities; engage openly with LGBT referral networks and identify LGBT-specific competencies on institution websites; develop protocols to support to LGBTQ physicians, staff , and patients who encounter antagonistic patients in clinical spaces; and expand formal continuing medical education (CME) offerings and staff development trainings on inclusive language use, LGBTQ+ identities, family structures, behaviors, and health needs beyond sexual health.[70–73] In general, physicians and nurses have few or no reservations about providing care to LGBTQ+ populations; however, they often feel unprepared to support LGBTQ+ patients across a range of health needs (emergency medicine, cancer care, dementia care, palliative care, etc.) given limited engagement with LGBTQ+ health in medical curricula,[74–79] even when they also identify as LGBT.[33] These changes will be a first step toward improving LGBTQ+ engagement with preventive services, reducing healthcare fragmentation, and ensuring the opportunity of access to all members of the LGBTQ+ community.

Longer-term, health systems can improve training and retention opportunities for LGBTQ+ health professionals by updating nondiscrimination policies to explicitly include sexual orientation and gender identity, and expanding fellowship and residency opportunities in LGBTQ+ health and medicine. Despite improvements since the 1990s, LGBT physicians continue to experience discrimination in the workplace, are denied referrals from colleagues, and witness discrimination against LGBT employees, patients, and patients' partners.[33] Physician workforce diversity matters for patient outcomes and reducing health disparities. Rigorous studies demonstrate that having a gender- or race-match between doctors and patients reduces mortality and adverse outcomes in hospital settings, increases uptake of preventive care, and increases patient satisfaction.[80,58,81,82] While not all LGBTQ+ patients may need or want to access an LGBTQ+ provider, LGBTQ+ health disparities may be improved by increasing training opportunities in LGBTQ+ medicine and for LGBTQ+ physicians, and by decreasing experiences of discrimination on the job that threaten retention of LGBTQ+ health professionals.[33]

### Limitations

While this study offers critical insight into potential benefits associated with access to an LGBTQ+ affirming provider for older LGBTQ+ adults in the U.S. South, there were some limitations. First, the item asking whether respondents had an LGBTQ+ affirming provider did not include a definition or example. LGBTQ+ adults may have had different perceptions of what "affirming" means in the context of health care. Future work should examine how patients identify whether their provider is culturally and clinically competent in LGBTQ+ health needs.

Second, while the VUSNAPS sample broadly reflects the characteristics of older LGBTQ+ adults in the U.S. South, the sample underrepresents the experiences of racial/ethnic minority, bisexual, and less educated members of the LGBTQ+ community who are often more likely to experience discrimination or erasure across multiple minority statuses, live in geographic locations with fewer affirming providers, and experience higher barriers to accessing care overall.[59,83,84]

Finally, data collection overlapped with the earliest period of the COVID-19 pandemic. The study mitigated the effects of the pandemic by measuring preventive care outcomes in the last 3 years to capture utilization prior to the onset of the pandemic. However, pandemic-related healthcare delays or restrictions may have still disrupted some preventive care.

## CONCLUSIONS

Expanding access to LGBTQ+ affirming providers across the health system may help narrow disparities in morbidity for LGBTQ+ older adults and intervene in the poorer health trajectories of LGBTQ people in many Southern states. To increase access to LGBTQ+ affirming providers, medical education and healthcare systems must expand formal and continuing education opportunities around LGBTQ+ medicine and adopt best practices for LGBTQ+ affirming care.

## ACKNOWLEDGMENTS

Note: Boldface indicates statistical significance. *p<0.1, **p<0.05, ***p<.01 LGBTQ+, lesbian, gay, bisexual, transgender, and queer; ns, nonsignificant.

[a]Gender identity was assessed using multiple domains, including current gender identity (multiple selection allowed), sex assigned at birth, a direct "are you transgender?" item, and, for transgender and other gender diverse respondents, daily presentation (man, woman, both, neither). Respondents are coded as transgender women when they identify as transgender and as a woman and were assigned male at birth.

[b]Respondents are coded as transgender men when they identify as transgender and as a man and were assigned female at birth.

[c]Respondents are coded as transgender nonbinary/gender nonconforming when they identify as transgender or nonbinary or gender nonconforming and do not also identify as a cisgender man or cisgender woman.

**Table 2.** Unadjusted Prevalence of Preventive Care and Chronic Disease Management Outcomes by Provider LGBTQ+ Affirming Status

| Arthritis or rheumatism | 169 (50) | 69 (50) | 100 (50) | 0.957 (0.759, 1.207) | 338 |

Note: Data come from Wave I VUSNAPS (R01AG063771). Boldface indicates statistical significance. *p<0.1, **p<0.05, ***p<.01 LGBTQ+, lesbian, gay, bisexual, transgender, and queer; ns, nonsignificant. Number is the raw count and % is the raw proportion. APR is the adjusted Prevalence Ratio adjusting for gender identity, race and ethnicity, sexual orientation, age, household income, education, state of residency and insurance status.

[a]All preventive care outcomes with the exception of HIV testing outcomes were adjusted for having any chronic condition, including high blood pressure or hypertension, diabetes or high blood sugar, heart attack or coronary heart disease, asthma, arthritis or rheumatism, a mental health condition, cancer, stroke, or HIV.

[b]All preventive and chronic disease management outcomes besides seeing a doctor in the last year were adjusted for having seen a doctor in the last year.

[c]HIV testing outcomes were restricted to cisgender men, transgender men, transgender women, and gender non- conforming individuals.

[d]Mammogram and Pap test outcomes were restricted to participants assigned female at birth.

| Level | Agent | Example |
|---|---|---|
| Interpersonal | Healthcare workers and clinicians | Cultural Competence:<br>• Gender inclusive language e.g. asking and sharing pronouns<br>• Pamphlet and health education materials including LGBTQ+ individuals<br>• Intentionally signaling safe environment e.g. wearing rainbow pin<br><br>Clinical Competence:<br>• Knowing Indication for and management of preexposure prophylaxis (PrEP)<br>• Sharing increased risk for colorectal cancer among gay and bisexual men<br>• Managing interaction of contraception and hormone replacement therapy |
| Institutional | Clinic and hospital leadership, DEI professionals, professional associations, and clinical educational programs | • Offering cultural and clinical competence courses for LGBTQ+ patients as part of core curriculum or continuing education opportunities.<br>• Supporting LGBTQ+ trainees by evaluating recruitment, retention, and promotion strategies.<br>• Reviewing healthcare plan coverage of gender affirming care, PreP, etc.<br>• Developing workflows that do not disrupt continuity of care amidst implementation of medical Religious Freedom Restoration Acts. |
| Structural | Government officials and policy makers | • Advocating for health insurance expansions, coverage of gender affirming care, and affordability of treatment for LGBTQ+ patients.<br>• Non-discrimination policies where LGBTQ+ people live, work, age, and play |

Adjusted Prevalence Ratio (Reference is Non-LGBTQ+ Affirming Provider)

Note: Census Household Pulse Survey (HPS) estimates incorporate data from Phase 3.2, Weeks 34 to 39, which covers the period of July 21, 2021, to October 11, 2021. We pool HPS data to account for smaller sample sizes among older adults and LGBTQ populations in the Southern US Census Region. Sample states include Alabama, Georgia, North Carolina, and Tennessee. For estimation purposes, the HPS sample is limited to older adults aged 50-76 at time of interview

who are cisgender and lesbian, gay, or bisexual, or who are transgender and any sexual orientation. Transgender includes individuals who self-identify their gender as "transgender" and any individual whose sex assigned at birth is different from their current gender identity. Estimates exclude individuals who report their sexual orientation as "Something Else or "Don't Know" who are not transgender. Differences between the VUSNAPS sample and estimates from HPS for Southern states of +/- 10 percentage points or more are bolded.
