ABSTRACT

Background: Hydrocephalus and myelomeningocele (MMC) place disproportionate burdens of disease on low and middle-income countries (LMICs). MMC-associated hydrocephalus and its sequelae result in a spectrum of severely devastating clinical manifestations, for which LMICs are disproportionately unprepared in terms of human, capital, and technological resources. This study aims to review and compare the management and outcomes of infant MMC-associated hydrocephalus in LMICs and high-income countries.

Methods: This study will follow the PRISMA 2020 guidelines. The following databases will be searched without restrictions on language, publication date, or country of origin: EMBASE, MEDLINE, The Cochrane Library, Global Index Medicus, African Journals Online, and ScieLO. All peer-reviewed studies of primary data reporting management and outcomes of infant MMC-associated hydrocephalus will be included. Where high-quality homogeneous studies exist, meta-analyses will be conducted to compare the management and outcomes of MMC-associated hydrocephalus across socioeconomic and geographic regions of the world. The primary outcome will be treatment failure of the first-line hydrocephalus treatment. Secondary outcomes include time to failure, rates of mortality, and postoperative complications.

Discussion: This study will generate evidence-based information on the management and outcomes of MMC-associated hydrocephalus across LMICs. Findings on our primary outcome will inform treatment decision-making; those on our secondary outcomes will synthesise the existing body of literature and help advocate for the ever-present need to improve access to safe, timely, and affordable neurosurgical care. This study will thus contribute to the global community of paediatric neurosurgery, particularly those practising in developing countries.

ARTICLE SUMMARY

Strengths and limitations of this study

- ② This review focuses on multiple treatment modes of a well-defined disease population.
- ② Six electronic databases that are commonly used across both high- and low-income countries will be searched.
- ② No restrictions on language, location, or publication date were placed during screening.
- ② Unpublished studies will not be sought.
- ② An interactive web application dashboard will be developed to facilitate the transparent interaction with our methods and findings and promote scientific discussion and scrutiny.

Keywords: Systematic Review; Meta-Analysis; Hydrocephalus; Meningomyelocele; Infant; Developing Countries; Outcome and Process Assessment, Health Care

INTRODUCTION

Hydrocephalus places a disproportionate burden of disease on low and middle-income countries (LMICs) (1, 2). It affects roughly 1 in 1,000 infants worldwide, but its incidence may exceed 200,000 cases per year in developing regions like sub-Saharan Africa (3). Myelomeningocele (i.e., meningomyelocele or open spina bifida; MMC) is a common and severe spinal aetiology and constitutes a significant proportion of this population (4-6). Its prevalence also varies by geography but approximates 113 cases per 100,000 births in LMICs (7, 8), reaching 77–610 and 700 cases per 100,000 births in South Africa and Nigeria, respectively. These disorders result in a spectrum of clinical manifestations, among which MMC-associated hydrocephalus is one of the most common and debilitating (4, 9, 10).

In LMICs, the incidence of MMC-associated hydrocephalus is high and can affect as many as 75% of cases (11, 12). Times to diagnoses and treatment are often delayed in these settings and, if treatment is not promptly initiated, most patients do not survive beyond infancy (4). Treatment may involve surgery, which is prone to significant morbidity and mortality, particularly in low-resource settings (1, 3). Intervening at the earliest stage with the best possible treatment remains, therefore, a crucial step in the management of MMC-associated hydrocephalus.

Ventriculoperitoneal (VP) shunts are the current standard of treatment and are, often, the only treatment available in LMICs (1). Increasingly, patients in high-income countries are being treated with endoscopic third ventriculostomy (ETV) or combinations of ETV and choroid plexus cauterization (CPC), whose success rates and perceptions are variable (1, 3, 4, 9). The uptake, time course, and success of these techniques in LMICs are, nonetheless, less clear but amenable to aggregation and review of the global literature.

STUDY AIMS AND OBJECTIVES

Aim

This study aims to review and compare the management and outcomes of MMC-associated hydrocephalus in infants across countries and treatment modes.

Objectives

To review and compare:

1. The first- and second-line use of VP shunts, combinations of ETV and CPC, and conservative management;
2. The rates and times to treatment failure of VP shunts, combinations of ETV and CPC, and conservative management; and
3. Measures of mortality and postoperative complications of VP shunts, combinations of ETV and CPC, and conservative management.

Review questions

Primary question:

1. What are the rates of failure of VP shunts, ETV, combinations of ETV and CPC, and conservative treatments in infant MMC-associated hydrocephalus?

Secondary questions:

2. What are the most frequent first- and second-line treatments in the management of infant MMC-associated hydrocephalus?
3. What is the time to failure of VP shunts, ETV, combinations of ETV and CPC, and conservative treatments in infant MMC-associated hydrocephalus?
4. What are the mortality and postoperative complication rates of VP shunts, ETV, combinations of ETV and CPC, and conservative treatments in infant MMC-associated hydrocephalus?
5. Are the management and outcomes of the MMC associated with the failure of the hydrocephalus treatment?

Subgroup analyses by country and treatment mode are planned (further details in **Methods** section). The primary outcome will be the rate of treatment failure of the first-line hydrocephalus treatment. Secondary outcomes include: time to failure, rates of mortality, and postoperative complications. Operational definitions of outcomes are provided in the **Methods**.

Due to its historical standing as the local standard of treatment, our principal hypothesis is that:

- H₁: VP shunts have the lowest rates of treatment failure in the infant MMC-associated hydrocephalus population.

Secondary hypotheses include:

- H₂: VP shunts are the most frequently used first-line treatment and have the lowest mortality and complication rates.
- H₃: Resource constrained environments are associated with late/worse MMC presentation amongst infants
- H₄: Late/worse MMC presentation is associated with high MMC treatment failure, mortality, and complication rates.
- H₅: MMC complication rates are associated with hydrocephalus treatment failure, mortality, and complication rates.

METHODS

This systematic review will be conducted following the guidelines outlined by the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) 2020 statement (13).

Search

A search strategy was developed to identify research articles on MMC-associated hydrocephalus. This was adapted from [McCarthy et al., 2019](#), and consisted of synonyms of 'hydrocephalus' and 'myelomeningocele' (**Supplementary Table 1**). The search was run on the following electronic databases, from inception until 5 October 2021: EMBASE, MEDLINE, The Cochrane Library, Global Index Medicus, African Journals Online, and ScieLO. No restrictions on language, location, or publication date were placed, and unpublished studies will not be sought. This search will be re-run prior to final analyses.

Study selection

Types of studies

We will include articles published in peer-reviewed journals with any of the following designs: original research, trials, cross-sectional and cohort studies, multiple case reports (i.e., >1 case), and case series. Opinion pieces, comments, letters, guidelines, editorials, single-case reports, reviews, meta-analyses, and qualitative studies will be excluded, as well as articles published in non-peer-reviewed journals.

Country income level

We will include studies whose data were collected in low-, lower-middle-, upper-middle-, and high-income economies, according to the World Bank Country and Lending Groups (14). Studies from high-income economies will be used as comparators. Studies whose data cannot be traced to one particular country will be excluded.

Types of participants

All studies of infants aged 2 years or younger with a clinical or imaging diagnosis of MMC-associated hydrocephalus will be included. Non-infants (i.e., >2 years) will be excluded, as will infants with diagnoses of lipomyelomeningocele, spina bifida occulta, or unspecified spina bifida, regardless of association with hydrocephalus.

Types of interventions

Studies of infants who have undergone either conservative (non-surgical) or surgical treatment for hydrocephalus will be included. These may include VP shunting, ETV, combined ETV and CPC, combined VP shunting and ETV, and combined VP shunting, ETV, and CPC. Studies of infants who underwent treatment for MMC, but not hydrocephalus, will be excluded.

Types of outcome measures

We will include studies of primary data reporting measures of treatment failure. In this review, treatment failure will be operationally defined as the performance of a second intervention for the same reason as the first. Studies reporting measures of mortality, morbidity, postoperative complications, and follow-up duration will also be included for secondary analysis. Post-operative complications will be defined as the unfavourable result of an intervention that did not result in treatment failure, and mortality as either 'intra-operative', if death occurred during a procedure, or 'perioperative', if it occurred within 30 days of surgery. For conservative treatments, mortality will encompass deaths that occurred within 30 days of administration.

Outcomes

The primary outcome of our study will be the rate of treatment failure for the first-line hydrocephalus treatment. Secondary outcomes will include time to failure, rates of mortality, and postoperative complications.

Study selection

Search results will be uploaded to Rayyan (<https://www.rayyan.ai>) to facilitate de-duplication and independent, blinded screening (15). First, titles and abstracts will be screened by two independent reviewers against the inclusion criteria, and the eligibility of the selected abstracts will be determined by reading the full texts. Unless otherwise stated, conflicts will be resolved through discussion and, where consensus cannot be achieved, through arbitration by the senior author (AF).

Data extraction

Two reviewers will independently extract and check the data extracted from the included studies using a standardised extraction proforma (**Supplementary Table 2**). Any disputes will be settled by a third reviewer (BDT, AYT, or AF). Data items will include information on study and sample characteristics; vertebral level of MMC and aetiology of hydrocephalus; clinical presentation and method of diagnosis; treatment mode, timing, and follow-up; and primary and secondary outcomes. If data is insufficiently provided in the full text, we will contact the corresponding author to request for the missing information and wait up to two months for a response. Following correspondence, all available data will be reported and studies with missing data will not be eligible for inclusion in the meta-analysis. All data will be recorded and stored in a spreadsheet.

Risk of bias assessment

Included studies will be assessed for risk of bias by two independent reviewers of the extraction team. Randomised studies will be assessed using Version 2 of the Cochrane risk-of-bias tool for randomised trials (RoB 2) (16). Non-randomised studies will be assessed using the ROBINS I tool (17). Risk of bias assessment will be used during the analysis and results presented in terms of the primary and secondary objectives of this study.

Data analysis

Following extraction, data will be transferred to Python for analysis. Screening results will be presented using a PRISMA flow diagram. Study and sample characteristics will then be summarised using descriptive statistics; these may include: vertebral level of MMC; aetiology of hydrocephalus; method of diagnosis; treatment mode; indication for surgery (if surgical management); timing, and follow-up; and primary and secondary outcomes.

The use, failure, and mortality measures of VP shunts, combinations of ETV and CPC, and conservative management will then be meta-analysed. Although meta-analyses are planned, these will only become apparent after data extraction is complete. Publication bias will be assessed through the use of funnel plots and Egger's test (18). If asymmetry is found in the funnel plot, the Trim-and-Fill method will be used to account for any potential publication bias (19). The overall estimates and 95% confidence intervals will be obtained using random-effects models as per established methods (20). Cochran's Q test ($P < 0.10$) and the I^2 statistic will be used to assess heterogeneity among studies (21). Unless otherwise stated, the statistical significance will be set at $P < 0.05$, and comparisons to high-income economies will be drawn.

Mortality, failure, and complication rates will however vary with hydrocephalus aetiology, age, mode of treatment, characteristics of MMC, and socioeconomic region. Therefore, subgroup analyses will be sought, as appropriate. A combination of dichotomous, proportion, continuous, O–E, and variance meta-analyses are planned for this purpose, as appropriate, depending on the data. Recognising that case reports may present unusual and/or protracted outcomes, and randomised trials may assess active interventions improving outcomes, analyses by study design are also planned.

Strength of body of evidence

The confidence in cumulative evidence included in this review will be assessed using the GRADE approach. Two independent reviewers will use the GRADEpro Guideline Development Tool (GRADEpro GDT) to assess the quality of outcomes of this study. A third reviewer (BDT, AYT, or JJP) will settle disagreements.

Ethics and dissemination

Ethics approval for this study was not applicable because this study did not involve human participants. Dissemination strategies will include publication in a peer-reviewed journal, oral and poster presentations at conferences, and an interactive web application to facilitate interaction with the findings and promote the discussion and sharing of findings on social media.

ACKNOWLEDGEMENTS

We thank Moniba Korch, Brian Ou Yong Ming, and Safia Farsana Shabeer for their contributions during the development and piloting of the extraction proforma.

AUTHOR CONTRIBUTIONS

BDT, AYT, and AF were responsible for conceiving the article. AF is the guarantor. BDT, AYT, JJP, and CG wrote the manuscript. AE, AF, BDT, AYT, CG, ERB, JJP, and SHL provided a critical appraisal of the manuscript. All authors critically revised and approved the final manuscript. BDT and AYT contributed equally and are joint first authors of the manuscript.

ETHICS APPROVAL

Ethics approval for this study was not applicable because this study did not involve human participants.

DATA AVAILABILITY STATEMENT

All data relevant to the study are included in the article or uploaded as supplementary information.

FUNDING

This work did not receive any funding.

COMPETING INTERESTS

None declared.
