### **Abstract:**

**Objective:** To determine whether the use of sodium-glucose cotransporter 2 (SGLT-2) inhibitors, compared to dipeptidyl peptidase 4 (DPP-4) inhibitors, is associated with a decreased risk of incident lung cancers among patients with type 2 diabetes.

**Methods:** We assembled a new-user, active comparator cohort of SGLT-2 inhibitor and DPP-4 inhibitor users using the United Kingdom Clinical Practice Research Datalink. We fit Cox proportional hazards models with propensity score fine stratification weighting to estimate hazard ratios (HRs) with 95% confidence intervals (CI) for incident lung cancers.

**Results:** Crude lung cancer incidence rates were 0.92 and 1.37 per 1,000 person-years among 47,517 SGLT-2 inhibitor and 129,807 DPP-4 inhibitor users, respectively. No reduced risk of lung cancer was observed among SGLT-2 inhibitor users after weighting (HR 1.08, 95% CI 0.78–1.48).

**Conclusions:** In this large cohort study, the use of SGLT-2 inhibitors was not associated with a decreased risk of lung cancer.

## **INTRODUCTION**

Laboratory studies have demonstrated that premalignant lesions and adenocarcinomas of the lung have increased expression of SGLT-2 [1, 2]. SGLT-2 inhibitors may therefore have a beneficial role in the prevention and treatment of lung cancer, potentially by affecting cell cycle arrest and apoptosis [3]. Animal models have shown that administering canagliflozin to mice with premalignant lesions of the lungs resulted in delayed tumour onset, a lower tumour burden, and prolonged survival, while administering canagliflozin to mice with lung adenocarcinoma patient-derived xenografts resulted in reduced tumour volume [1]. However, no studies to date have investigated the association between the use of SGLT-2 inhibitors and lung cancer risk in humans. We conducted a retrospective cohort study to assess whether SGLT-2 inhibitor use, when compared to dipeptidyl peptidase-4 (DPP-4) use, is associated with a decreased risk of lung cancer in individuals with type 2 diabetes.

## **METHODS**

To investigate this relationship, we sourced data from the United Kingdom (UK) Clinical Practice Research Datalink (CPRD) [4]. We assembled a cohort of patients newly prescribed an SGLT-2 inhibitor (canagliflozin, empagliflozin, dapagliflozin, ertugliflozin) or a DPP-4 inhibitor (alogliptin, linagliptin, saxagliptin, sitagliptin, vildagliptin) between 1 January 2013 (the year when SGLT-2 inhibitors became available in the UK) and 31 December 2019. Cohort entry was the date of the first-ever prescription for an SGLT-2 inhibitor or DPP-4 inhibitor during the study period. We excluded patients less than 18 years of age, with less than one year of medical history, with a history of any cancer other than non-melanoma skin cancer, or with less than 6 months of follow-up.

Patients were followed starting six months after cohort entry to account for latency of the effect of SGLT-2 inhibitor use on lung cancer. Patients were censored upon the first occurrence of an incident lung cancer diagnosis, death from any cause, end of registration with the CPRD, or end of the study period (30 June 2020).

Our models considered a broad range of potential confounders measured at or before cohort entry, including age, sex, calendar year, body mass index, smoking status, hemoglobin A1c, alcohol-related disorders, duration of diabetes, previous use of antidiabetic drugs, proxy variables for diabetes severity such as macrovascular and microvascular complications, history of lung diseases, common comorbidities, medication use, and markers for health-seeking behaviour such as cancer screening and vaccination. A missing variable category was used for missing covariate data as missing data was unlikely to be differential between exposure groups.

We generated propensity scores for all participants using multivariable logistic regression to predict the probability of using SGLT-2 inhibitors compared to DPP-4 inhibitors conditional on all covariates listed in Table 1. We used propensity score fine stratification weighting to control for confounding and generated 50 strata of patients based on the propensity score distribution of the SGLT-2 inhibitor users. We used descriptive statistics to assess balance between groups using standardised differences and considered differences of less than 0.10 to be acceptable.

We calculated incidence rates of lung cancer and 95% confidence intervals (95% CIs) based on the Poisson distribution in both exposure groups over the follow-up period. We fit weighted Cox proportional hazards models to estimate the hazard ratio (HR) and 95% CI of lung cancer incidence in SGLT-2 inhibitor users compared to DPP-4 inhibitor users. We additionally assessed whether there is a duration-response relationship between SGLT-2 inhibitor use and lung cancer incidence, whether the relationship between SGLT-2 inhibitor use and lung cancer

incidence varies within the individual drugs in the class, and whether smoking acts as an effect modifier for the relationship between SGLT-2 inhibitor use and lung cancer. Finally, we conducted four sensitivity analyses: 1) varying the six-month lag period to twelve-month and eighteen-month periods, 2) conducting an as-treated analysis such that patients were censored upon drug discontinuation or prescription of a drug from the opposite exposure group, 3) using GLP-1 receptor agonist users as the comparator group rather than DPP-4 inhibitor users, and 4) using inverse probability of censoring weighting to account for potential differences in mortality and censoring between the two exposure groups.

The study was approved by the CPRD Independent Scientific Advisory Committee (protocol 22\_001710).

## **RESULTS**

We followed 47,517 SGLT-2 inhibitor users for a median of 2.00 years and 129,807 DPP-4 inhibitor users for a median of 2.84 years (Figure 1). The cohort was well balanced with respect to covariates (Table 1). The crude incidence rates of lung cancer were 91.88 and 136.98 per 100,000 person-years among SGLT-2 inhibitor users and DPP-4 inhibitor users, respectively (Table 2). After weighting, no decreased risk of lung cancer was observed among SGLT-2 inhibitor users (HR 1.08, 95% CI 0.78–1.48).

There was little evidence of a duration-response relationship. For cumulative durations of less than six months, six to twelve months, and greater than twelve months of SGLT-2 inhibitor use, weighted hazard ratios were 0.99 (95% CI 0.59–1.67), 0.98 (95% CI 0.58–1.64), and 1.17 (95% CI 0.81–1.69), respectively. The relationship between SGLT-2 inhibitor use and lung cancer did not vary by SGLT-2 inhibitor molecule (HR 1.22 (95% CI 0.71–2.10) for canagliflozin, HR 0.93 (95% CI 0.62–1.38) for dapagliflozin, HR 1.30 (95% CI 0.81–2.09) for empagliflozin). Effect

modification by smoking was not evident (HR 0.66 (95% CI 0.14–3.14) among non-smokers, HR 1.10 (95% CI 0.80–1.51) among ever-smokers).

Our estimates remained consistent when varying the lag period from six months to twelve months (HR 1.14, 95% CI 0.81–1.60) and eighteen months (HR 1.10, 95% CI 0.66–1.58). There was little effect of censoring patients upon drug discontinuation or prescription of a drug from the opposite exposure group (HR 0.98, 95% CI 0.70–1.39). Estimates remained similar when comparing SGLT-2 inhibitor users to GLP-1 receptor agonist users instead of DPP-4 inhibitor users (HR 1.02, 95% CI 0.64–1.63). Finally, our estimates were similar when using inverse probability of censoring weighting (HR 0.99, 95% CI 0.71–1.37).

## CONCLUSIONS

This large cohort study was the first to assess the relationship between SGLT-2 inhibitor use and the risk of lung cancer in humans. The results of this study do not suggest that the use of SGLT-2 inhibitors, compared to DPP-4 inhibitors, is associated with a decrease in the short-term risk of lung cancer. Further research on this association with a longer follow-up period may be warranted.

**Data availability:** No data are available. This study is based on data from the Clinical Practice Research Datalink obtained under license from the UK Medicines and Healthcare products Regulatory Agency. The data are provided by patients and collected by the UK National Health Service as part of their care and support. The interpretation and conclusions contained in this study are those of the author/s alone. Because electronic health records are classified as “sensitive data” by the UK Data Protection Act, information governance restrictions (to protect patient

confidentiality) prevent data sharing via public deposition. Data are available with approval through the individual constituent entities controlling access to the data. Specifically, the primary care data can be requested via application to the Clinical Practice Research Datalink (<https://www.cprd.com>).

**Funding:** This research was funded by a Foundation Scheme grant from the Canadian Institutes of Health Research (FDN-143328). S.B.S. is the recipient of a doctoral training award from the Fonds de recherche du Québec - Santé. O.Y. holds a Chercheur-Boursier Clinicien Junior 1 award from Fonds de Recherche du Québec – Santé. L.A. holds a Chercheur-Boursier Senior award from Fonds de Recherche du Québec – Santé and is the recipient of a William Dawson Scholar Award from McGill University. The study sponsor/funder was not involved in the design of the study; the collection, analysis, and interpretation of data; writing the report; and did not impose any restrictions regarding the publication of the report.

**Conflicts of interest:** L.A. received consulting fees from Janssen and Pfizer unrelated to this project. No other potential conflicts of interest relevant to this article were reported.

**Author contributions:** S.B.S. wrote the first draft of the manuscript, and all authors edited, reviewed, and approved the final version of the manuscript. All authors conceived and designed the study, analyzed and interpreted the data, approved the final version of the manuscript, and are accountable for its accuracy. S.B.S., H.Y., and L.A. performed the statistical analyses. L.A. acquired the data and supervised the study. L.A. is the guarantor of this work and, as such, had full access to all the data in the study and takes responsibility for the integrity of the data and the accuracy of the data analysis.
